

LIMIT THEOREMS FOR POINT PROCESSES UNDER GEOMETRIC CONSTRAINTS (AND TOPOLOGICAL CRACKLE)

BY TAKASHI OWADA[†] AND ROBERT J. ADLER^{*,†}

Technion – Israel Institute of Technology

We study the asymptotic nature of geometric structures formed from a point cloud of observations of (generally heavy tailed) distributions in a Euclidean space of dimension greater than one. A typical example is given by the Betti numbers of Čech complexes built over the cloud. The structure of dependence and sparsity (away from the origin) generated by these distributions leads to limit laws expressible via non-homogeneous, random, Poisson measures. The parametrisation of the limits depends on both the tail decay rate of the observations and the particular geometric constraint being considered.

The main theorems of the paper generate a new class of results in the well established theory of extreme values, while their applications are of significance for the fledgling area of rigorous results in topological data analysis. In particular, they provide a broad theory for the empirically well-known phenomenon of homological ‘crackle’; the continued presence of spurious homology in samples of topological structures, despite increased sample size.

1. Introduction. The main results in this paper lie in two seemingly unrelated areas, those of classical Extreme Value Theory (EVT), and the fledgling area of rigorous results in Topological Data Analysis (TDA).

The bulk of the paper, including its main theorems, are in the domain of EVT, with many of the proofs coming from Geometric Graph Theory. However, the consequences for TDA, which will not appear in detail until the penultimate section of the paper, actually provided our initial motivation, and so we shall start with a brief description of this aspect of the paper.

Many problems in TDA start with a ‘point cloud’, a collection $\mathcal{X} = \{x_1, \dots, x_n\}$ of points in $\mathbb{R}^d$, from which more complex sets are constructed. Two simple examples are the simple union of balls

$$U(\mathcal{X}, r) \triangleq \bigcup_{k=1}^n B(x_k; r),$$

Keywords and phrases: Point process, Poisson random measure, extreme value theory, regular variation, Čech complex, Betti number, topological data analysis, crackle, geometric graph.

where $B(x; r)$ is a closed ball of radius r about the point x , and the Čech complex, $\check{C}(\mathcal{X}, r)$.

DEFINITION 1.1. *Let $\mathcal{X}$ be a collection of points in $\mathbb{R}^d$ and r be a positive number. Then the Čech complex $\check{C}(\mathcal{X}, r)$ is defined as follows.*

1. *The 0-simplices are the points in $\mathcal{X}$.*
2. *A p -simplex $\sigma = [x_{i_0}, \dots, x_{i_p}]$ belongs to $\check{C}(\mathcal{X}, r)$ whenever a family of closed balls $\{B(x_{i_j}; r/2), j = 0, \dots, p\}$ has a nonempty intersection.*

Čech complexes are higher-dimensional analogues of *geometric graphs*, a notion more familiar to probabilists.

DEFINITION 1.2. *Given a finite set $\mathcal{X} \subset \mathbb{R}^d$ and a real number $r > 0$, the geometric graph $G(\mathcal{X}, r)$ is the undirected graph with vertex set $\mathcal{X}$ and edges $[x, y]$ for all pairs $x, y \in \mathcal{X}$ for which $\|x - y\| \leq r$.*

For a given a Čech complex, it is immediate from the definitions that its 1-skeleton is actually a geometric graph. Examples of both are given in Figure 1.

FIG 1. Take $\mathcal{X} = \{x_1, \dots, x_8\} \subset \mathbb{R}^2$. Note that the 2-simplex $[x_1, x_2, x_3]$ belongs to $\check{C}(\mathcal{X}, r)$, since the three balls with radius r centred at x_1, x_2, x_3 have a common intersection. The Betti numbers of $\check{C}(\mathcal{X}, r)$ are $\beta_0 = 1$ (one connected component), $\beta_1 = 2$ (two closed loops), while all others are zero. The geometric graph $G(\mathcal{X}, r)$ shows the 1-skeleton of $\check{C}(\mathcal{X}, r)$.

A typical TDA paradigm is to create either $U(\mathcal{X}, r)$ or $\check{C}(\mathcal{X}, r)$ as an estimate of some underlying sub-manifold, $\mathcal{M} \subset \mathbb{R}^d$, from which $\mathcal{X}$ is actually sampled, and then consider its homology, typically via what is known as persistent homology (with which we shall not concern ourselves in this paper) or through Betti numbers.

We shall concern ourselves primarily with Betti numbers, a basic quantifier in Algebraic Topology. Roughly speaking, given a topological space X , the 0-th Betti number $\beta_0(X)$ counts the number of its connected components, while for $k \geq$

1, the k -th Betti number $\beta_k(X)$ counts the number of k -dimensional ‘holes’ or ‘cycles’ in X . For example, a one-dimensional sphere – i.e. a circle – has $\beta_0 = 1$, $\beta_1 = 1$, and $\beta_k = 0$ for all $k \geq 2$. A two-dimensional sphere has $\beta_0 = 1$, $\beta_1 = 0$, and $\beta_2 = 1$, and all others zero. In the case of a two-dimensional torus, the non-zero Betti numbers are $\beta_0 = 1$, $\beta_1 = 2$, and $\beta_2 = 1$. At a more formal level, $\beta_k(X)$ can be defined as the dimension of the k -th homology group, however the essence of this paper can be captured without knowledge of homology theory. In the sequel, simply viewing $\beta_k(X)$ as the number of k -dimensional holes will suffice. The readers who are interested in a thorough coverage of homology theory may refer to [15] or [27].

Returning to the two sets $U(\mathcal{X}, r/2)$ and $\check{C}(\mathcal{X}, r)$, by a classical result known as the Nerve Theorem ([9]) they are homotopy equivalent, and so from the point of view of TDA they are conceptually equivalent. However, since the definition of the Čech complex is essentially combinatorial, it is computationally more accessible, and so of more use in applications. Hence we shall concentrate on it from now on.

There is now a substantial literature, with [18, 19] being the papers that motivated us, that shows that, given a nice enough $\mathcal{M}$, and any $\delta > 0$, there are explicit conditions on n and r such that the homologies of U and $\check{C}$ are equal to the homologies of $\mathcal{M}$ with a probability of at least $(1 - \delta)$. Typically, these results hold when the sample $\mathcal{X}$ is either taken from $\mathcal{M}$ itself, or from $\mathcal{M}$ with small (e.g. Gaussian) random, perturbative error. However, if the error is allowed to become large (e.g. has a heavy tailed distribution) then these results fail, and a phenomenon known as *crackle* occurs. An example is given in Figure 2, taken from [1], in which the underlying $\mathcal{M}$ (a stratified manifold in this case) is an annulus in $\mathbb{R}^2$. From the point of view of TDA, the main aim of the current paper is to derive rigorous results describing the distribution of the ‘extraneous homology elements’ appearing in Figure 2(d).

These results, as central as they are to the paper, will be given in detail only in Section 5. There we shall show that the Betti numbers of the sets generating this spurious homology, which occurs far from the support of $\mathcal{M}$, satisfy Poisson limit laws. The limit laws are stated in terms of the distance of these sets from $\mathcal{M}$, so that they are in terms of limiting Poisson laws, the intensities of which depend significantly on the tail decay rate of the perturbative error. The practical importance of this is that it gives useful information on *how much* crackle occurs, what its *topological nature* is, and *where* it occurs, at least in a limiting scenario. The results of Section 5, therefore, are the main ones from the point of view of TDA.

The reason that we need to wait so long to get to these results is that the natural probabilistic setting for both stating and proving the theorems from which they follows is that of EVT. Recall that the classical setup of (multivariate) EVT takes a

FIG 2. (a) The original space $\mathcal{M}$ (an annulus) that we wish to recover from random samples. (b) With the appropriate choice of radius, we can easily recover the homology of the original space from the union of balls around a random sample from $\mathcal{M}$. (c) In the presence of bounded noise, homology recovery is undamaged. (d) In the presence of unbounded noise, many extraneous homology elements appear, and significantly interfere with homology recovery.

point process generated by independently and identically distributed (i.i.d.) random variables in $\mathbb{R}^d$ – a random point cloud – scales and centers the cloud, and then, typically, shows weak convergence of the new cloud to a Poisson random measure. The literature dealing with this setup is rich, and impossible to summarise here, but the main references for EVT are probably [14], [22], and [24], while a comprehensive introduction to point process theory is provided by [11].

Beyond these more classical papers, over the last decade or so there have been a number of papers treating geometric descriptions of multivariate extremes from the perspective of point process theory, among them [4], [5], and [6]. In particular, Poisson limits of point processes possessing a U-statistic structure were investigated by [10] and [26], the latter also treating a number of examples in stochastic geometry.

All of these papers focused on the (limiting) distributions of extreme sample clouds, but so far, surprisingly few attempts have been made at analyzing their topological features. The objective of the present work is to present a unified, geometric, and topological approach to the point process convergence of extreme sample clouds. Results on the limiting behaviour of geometric complexes are quite new, with results not unrelated to our own, include [16], [17], [28], and [29]. In

particular [17] and [29] derived various central and Poisson limit theorems for the Betti numbers of the random Čech complexes $\check{C}(\mathcal{X}_n, r_n)$, with $\mathcal{X}_n$ a random point set in $\mathbb{R}^d$ and r_n a threshold radius. The resulting limit theorems depend heavily on the asymptotics of nr_n^d , as $n \rightarrow \infty$. For example, [17] investigated the *sparse regime* (i.e. $nr_n^d \rightarrow 0$) so that the spatial distribution of complexes is sparse, and they are observed mostly as isolated components. In contrast, the main focus of [29] was the *thermodynamic regime* (i.e. $nr_n^d \rightarrow \xi \in (0, \infty)$) in which complexes are large and highly connected.

However, with the single exception of [1], already discussed above, none of these papers has results related to crackle. The main discovery of [1] was that the topological behaviour of the individual components of geometric complexes built over point clouds of (typically) heavy tailed random variables is determined by how far away they lie from $\mathcal{M}$. In the simple case in which $\mathcal{M}$ is a single point at the origin, this is exhibited by the formation of ‘rings’ around the origin, each ring containing points of the cloud which exhibit quite different geometric and topological properties. The positions of the rings depend crucially on the tail decay rate of the underlying probability distribution of the observations as well as the topological property being studied. The contribution of the present paper is to take the discovery of [1], made on the basis of only two examples, and develop it into a full theory, covering wide classes of distributions and developing far more detailed descriptions of the crackle phenomenon.

The remainder of the paper is structured as follows: In Section 2, we establish general results on point process convergence under certain geometric constraints. Since the results here are very general, the conditions of the theorems may at first seem rather unnatural and hard to check. That this is actually not the case becomes clear when we turn to specific scenarios depending on the tail properties of the underlying distributions. In doing so, it turns out to be natural to distinguish between what we shall henceforth call ‘heavy-tailed’ (e.g. power law tails) and ‘light-tailed’ (e.g. $e^{-||x||^\tau}$, $\tau > 0$) densities. Section 3 defines heavy-tailed densities more precisely, via regular variation of tails (giving marginal distributions in the max-domain of attraction of the Fréchet law) and then applies the general results of Section 2 to obtain limiting Poisson results for this case. Section 4 then does the same for light-tailed densities (with tails controlled by the von Mises function). Typically, a standard argument in EVT characterises distributional tails via distribution functions (not densities), but our calculation will proceed relying heavily on the treatment of densities. Therefore, in both Sections 3 and 4, we shall distinguish the underlying distributions using density functions.

The final Section 5 presents several applications of the point process convergence, one of which is the limit theory of Betti numbers alluded to above. In addition, we give some independently interesting limit theorems on partial sums and

maxima under geometric constraints. To the best of our knowledge, these results have no precursors in the random topology literature, since, while they are simple corollaries of the Poisson convergence that is our main theme, proving them *ab initio* would be quite hard.

A final remark is that all random points in the present paper are generated from an inhomogeneous Poisson point process in $\mathbb{R}^d$ with intensity nf (f is a density function). However, all the results obtained can be carried over to the situation of an i.i.d. random sample without difficulty. Further, we only consider spherically symmetric densities. Although the spherical symmetry assumption has very little to do with our results, we adopted it in order to avoid unnecessary technicalities, which would otherwise blur the message of the paper as well as making the treatment much longer and more cumbersome.

Since the paper is rather long, and unavoidably heavy on notation, we conclude the Introduction with a short notation guide.

2. Point Process Convergence: General Theory. In this section we prove a general convergence result for point processes with geometric constraints. The main result, Theorem 2.1, which holds under somewhat opaque conditions, will then be applied in the two following sections to obtain results under specific, and quite natural, distributional assumptions. Before getting to results, however, we need to set up a framework and notation, which we do in the following subsections.

2.1. Point clouds and indicator functions for geometry. We start with a collection $\mathcal{X} = \{X_i, i \geq 1\}$ of i.i.d., $\mathbb{R}^d$ -valued random variables with spherically symmetric probability density f . For $n \geq 1$, let N_n be a Poisson random variable with mean n , and independent of the X_i . Then the random measure with atoms at the points $X_1, \dots, X_{N_n}$, which we denote by $\mathcal{P}_n$, is an inhomogeneous Poisson point process with intensity nf .

Now choose a positive integer k , which will remain fixed for the remainder of the paper. Although some of our results hold for $k = 1$, we shall henceforth take $k \geq 2$, unless otherwise stated. As will soon be clear, in the $k = 1$ case many of the objects and functions we build will degenerate, in the sense that the corresponding results will become known results of non-topological EVT.

Let

$$(2.1) \quad \mathcal{X}_k \triangleq \{X_1, \dots, X_k\}$$

be the first k points and for an ordered k -tuple $\mathbf{i} = (i_1, \dots, i_k)$, $1 \leq i_1 < \dots < i_k$, consider the k -tuple of points

$$(2.2) \quad \mathcal{X}_{\mathbf{i}} \triangleq \{X_{i_1}, \dots, X_{i_k}\}.$$

Symbol	Definition or Meaning	Place Defined
$\bar{C}(\mathcal{X}, r)$	Cech complex	Definition 1.1
$G(\mathcal{X}, r)$	Geometric graph	Definition 1.2
$\mathcal{X}$	Point cloud $\{X_1, \dots\}$	
$\mathcal{P}_n$	Poisson point process with intensity nf	
$\mathcal{X}_k$	First k points in $\mathcal{X}$	(2.1)
$\mathcal{X}_i, \mathbf{i} = \{i_1, \dots, i_k\}$	Subset $\{X_{i_1}, \dots, X_{i_k}\}$ of $\mathcal{X}$	(2.2)
$\mathcal{I}_{n,k}$	All subsets of $\{1, \dots, n\}$ of size k	(2.3)
$r_n, c_{k,n}, d_{k,n}, R_{k,n}$ etc.	Scaling sequences, specific to section	
$X_i^{(n)}$	X_i , translated and scaled	(2.10)
$\mathcal{X}_k^{(n)}$	First k points of normalised X_i s	(2.11)
$\mathcal{X}_i^{(n)}, \mathbf{i} = \{i_1, \dots, i_k\}$	Subset $\{X_{i_1}^{(n)}, \dots, X_{i_k}^{(n)}\}$	(2.12)
$S(x)$	Maps $x \in \mathbb{R}^d$ onto +ve orthant of S^{d-1}	(2.13)
L_k	Upper-diagonal subset of a k -dim. cube	(2.14)
$N_n^{(k)}$	No. of k -tuples satisfying a condition	(2.15)
$\tilde{N}_n^{(k)}$	No. of <i>isolated</i> k -tuples as above	(2.16)
$p(\mathbf{x}; r)$	Local integral of density	(3.7)
$J(\theta)$	Polar Jacobian	(4.9)
$x \preceq y$, for $x, y \in \mathbb{R}^d$	$x_i \leq y_i, i = 1, \dots, d$	
$x \prec y$, for $x, y \in \mathbb{R}^d$	$x_i < y_i, i = 1, \dots, d$	
$a \vee b$, for $a, b \in \mathbb{R}$	$\max\{a, b\}$	
$a \wedge b$, for $a, b \in \mathbb{R}$	$\min\{a, b\}$	
$B(x; r)$	Ball, centre x , radius r	
$\ \cdot\ $	Euclidean norm	
S^d	d -dimensional unit radius sphere	
s_d	Surface area of S^d	
λ_k	k -dimensional Lebesgue measure	
$Poi(\lambda)$	Poisson distribution with mean λ	
$\Rightarrow$	Weak convergence	
$\mathbf{0}$	Vector of zeros	
e_1	Vector with 1st comp. 1 and others zero	
$\text{Ann}(a, b)$	Annulus, $\{x \in \mathbb{R}^d : a \leq \ x\ \leq b\}$	

We are interested in the geometric objects built over the $\mathcal{X}_i$, for all $\mathbf{i}$ in the set $\mathcal{I}_{|\mathcal{P}_n|,k}$, where

$$(2.3) \quad \mathcal{I}_{m,k} \triangleq \{\mathbf{i} = (i_1, \dots, i_k) : 1 \leq i_1 < \dots < i_k \leq m\},$$

and $|\mathcal{P}_n| = N_n$ is the number of atoms of $\mathcal{P}_n$.

To set this up formally, we define an indicator function $h : (\mathbb{R}^d)^k \rightarrow \{0, 1\}$ which will capture the geometry. Two concrete examples related to problems that will be considered in detail later sections are

$$(2.4) \quad h(x_1, \dots, x_k) = \mathbf{1}(G(\{x_1, \dots, x_k\}, 1) \cong \Gamma),$$

and

$$(2.5) \quad h(x_1, \dots, x_k) = \mathbf{1}(\beta_{k-2}(\check{C}(\{x_1, \dots, x_k\}, 1)) = 1),$$

where $\mathbf{1}$ is the indicator function, G is a geometric graph, Γ is a fixed connected graph with k vertices, $\cong$ denotes graph isomorphism, and $\check{C}$ is a Čech complex.

Throughout the paper we shall require that h is shift invariant, viz.

$$(2.6) \quad h(x_1, \dots, x_k) = h(x_1 + y, \dots, x_k + y), \quad \text{for all } x_1, \dots, x_k, y \in \mathbb{R}^d.$$

We shall refer to this as the *shift invariance condition in what follows*. Further, we shall typically require a *points in proximity condition*, defined by the requirement that there exists a finite $M > 0$ for which

$$(2.7) \quad h(0, x_1, \dots, x_{k-1}) = 0 \text{ if } \|x_i\| > M \text{ for some } i \in \{1, \dots, k-1\}.$$

In addition, given a non-increasing sequence of positive numbers $(r_n, n \geq 1)$ (the case $r_n \equiv \text{constant}$ is permissible) we define scaled versions of h , $h_n : (\mathbb{R}^d)^k \rightarrow \{0, 1\}$, by setting

$$(2.8) \quad h_n(x_1, \dots, x_k) \triangleq h(x_1/r_n, \dots, x_k/r_n).$$

Clearly, h_n is also shift invariant. Furthermore, if r_n is small, then (2.7) implies that $h_n(x_1, \dots, x_k) = 1$ only when all the points $x_1, \dots, x_k$ are close to one another.

In what follows, we shall be particularly interested in k -tuples $\mathcal{X}_{\mathbf{i}}$, $\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}$ which not only satisfy the constraint implicit in the indicator h_n but are also separated (by at least r_n) from the other points in $\mathcal{P}_n$. Thus, we need to introduce another sequence of indicator functions. Given a subset $\mathcal{X}$ of k points in $\mathbb{R}^d$, and a larger, but finite, set $\mathcal{Y} \supset \mathcal{X}$ of points in the same space, define

$$(2.9) \quad g_n(\mathcal{X}, \mathcal{Y}) \triangleq h_n(\mathcal{X}) \times \mathbf{1}(G(\mathcal{X}, r_n) \text{ is an isolated component of } G(\mathcal{Y}, r_n)).$$

2.2. Sequences of point processes. Since we are going to be dealing with the geometry of random variables ‘in the tail’ of f , as in standard EVT we are going to need to normalise them before trying to formulate any results.

Thus, with k still fixed, we assume that we have two sequences of constants, $d_{k,n} \in \mathbb{R}$ and $c_{k,n} > 0$, with which to shift and then scale the X_i , and, in notations that will save a lot of space, define:

$$(2.10) \quad X_i^{(n)} \triangleq \frac{X_i - d_{k,n} S(X_i)}{c_{k,n}}$$

$$(2.11) \quad \mathcal{X}_k^{(n)} \triangleq \{X_1^{(n)}, \dots, X_k^{(n)}\}$$

$$(2.12) \quad \mathcal{X}_{\mathbf{i}}^{(n)} \triangleq \{X_{i_1}^{(n)}, \dots, X_{i_k}^{(n)}\}$$

where

$$(2.13) \quad S(x) \triangleq \frac{(|x^{(1)}|, \dots, |x^{(d)}|)}{\|x\|}$$

maps points $x = (x^{(1)}, \dots, x^{(d)})$ in $\mathbb{R}^d$ onto the positive orthant of S^{d-1} .

We can now define the two random measures, that will be at the centre of all that follows, over the space $E_k \times L_k$, where E_k is a measurable set in $([-\infty, \infty]^d)^k$ and L_k is the upper-diagonal subset of a k -dimensional cube, viz.

$$(2.14) \quad L_k \triangleq \{(z_1, \dots, z_k) \in [0, 1]^k : 0 \leq z_1 < \dots < z_k \leq 1\}.$$

The measures, for Borel $A \subset E_k \times L_k$, and ϵ_x a Dirac measure at $x \in E_k \times L_k$, are given by

$$(2.15) \quad N_n^{(k)}(A) \triangleq \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} h_n(\mathcal{X}_{\mathbf{i}}) \epsilon_{(\mathcal{X}_{\mathbf{i}}^{(n)}, \mathbf{i}/|\mathcal{P}_n|)}(A),$$

and

$$(2.16) \quad \tilde{N}_n^{(k)}(A) \triangleq \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) \epsilon_{(\mathcal{X}_{\mathbf{i}}^{(n)}, \mathbf{i}/|\mathcal{P}_n|)}(A).$$

(Note that $N_n^{(k)} = \tilde{N}_n^{(k)} \equiv 0$ whenever $k > n$.)

The point process $N_n^{(k)}$ counts k -tuples satisfying the geometric condition implicit in h_n , while $\tilde{N}_n^{(k)}$ adds the additional restriction that the geometric graphs generated by such k -tuples be distance at least r_n from all the remaining points of $\mathcal{P}_n$. It will turn out that, while $N_n^{(k)}$ always dominates $\tilde{N}_n^{(k)}$, both exhibit very similar limiting behaviour. In fact, the proof of the general result on point process convergence will follow the route of first establishing a result for $N_n^{(k)}$, which is somewhat easier because the geometric condition implicit in the indicator does not include $\mathcal{P}_n$, and then showing that since the two processes are close to one another the same limit holds for $\tilde{N}_n^{(k)}$.

2.3. A general theorem. Retaining the notation of the previous subsection, we now set up the main conditions that will ensure the weak convergence of the processes $N_n^{(k)}$ and $\tilde{N}_n^{(k)}$. Although we ultimately want theorems in which conditions relate to the tail behaviour of the underlying density of the X_i , the conditions in this section relate both to this and to what amounts to asymptotic sparsity for certain structures in $\mathcal{P}_n$. In Sections 3 and 4 we shall see how to derive this independence from tail considerations.

For our first condition, which we refer to as the *vague convergence condition*, we assume that there exist a Radon measure ν_k on a measurable set $E_k \subset ([-\infty, \infty]^d)^k$, not assigning mass to points at infinity, and normalising constants, as in the previous subsection, such that

$$(2.17) \quad \binom{n}{k} \mathbb{P} \left\{ h_n(\mathcal{X}_k) = 1, \mathcal{X}_k^{(n)} \in \cdot \right\} \xrightarrow{v} \nu_k(\cdot),$$

where $\xrightarrow{v}$ denotes vague convergence in E_k .

The second, *sparsity condition*, is given by

$$(2.18) \quad n^{2k-l} \mathbb{P} \left\{ h_n(\mathcal{X}_k) = h_n(X_1, \dots, X_l, X_{k+1}, \dots, X_{2k-l}) = 1, \mathcal{X}_{2k-l}^{(n)} \in K \right\} \rightarrow 0,$$

as $n \rightarrow \infty$, for every $l = 1, \dots, k-1$ and every compact set K in E_{2k-l} . This condition prevents the random k -tuples from clustering too much, and will lead to a Poisson limit for $N_n^{(k)}$. The same kind of sparsity, or anti-clustering, condition can be found in, for example, [10] and [26].

An additional condition will be needed for the convergence of $\tilde{N}_n^{(k)}$. For this, let $\mathcal{P}'_n$ be an independent copy of $\mathcal{P}_n$. Then this condition, combined with (2.17), requires that, asymptotically in n , the k points in $\mathcal{X}_k$ all be distance at least r_n from the points in $\mathcal{P}'_n$. Specifically,

$$(2.19) \quad \binom{n}{k} \mathbb{P} \left\{ g_n(\mathcal{X}_k, \mathcal{X}_k \cup \mathcal{P}'_n) = 1, \mathcal{X}_k^{(n)} \in \cdot \right\} \xrightarrow{v} \nu_k(\cdot).$$

As one might expect from these conditions, when they hold the weak limits of $N_n^{(k)}$ and $\tilde{N}_n^{(k)}$ will typically be expressible via Poisson random measures, which we denote by $N^{(k)}$, and now define.

Writing λ_k for k -dimensional Lebesgue measure, the Poisson random measure $N^{(k)}$ on $E_k \times L_k$, with mean measure $\nu_k \times \lambda_k$ (with λ_k restricted to L_k) is defined by the finite dimensional distributions

$$\mathbb{P}(N^{(k)}(A) = m) = e^{-(\nu_k \times \lambda_k)(A)} ((\nu_k \times \lambda_k)(A))^m / m!, \quad m = 0, 1, 2, \dots,$$

for all measurable $A \subset E_k \times L_k$ with $(\nu_k \times \lambda_k)(A) < \infty$. Furthermore, if $A_1, \dots, A_m$ are disjoint subsets in $E_k \times L_k$, then $N^{(k)}(A_1), \dots, N^{(k)}(A_m)$ are independent.

The random measures $N_n^{(k)}$, $\tilde{N}_n^{(k)}$, and $N^{(k)}$ are all regarded as random elements in the space $M_p(E_k \times L_k)$ of Radon point measures in $E_k \times L_k$. Details on such random measures, including issues related to their weak convergence in the space of Radon measures, along with the vague convergence of (2.17) and (2.19), can be found, for example, in [22] and [23].

Before stating the main result of this section, a few words about the above three conditions are in order. Firstly, we note that more specific definitions of the state space E_k and concrete definitions of the normalising constants $(c_{k,n}, d_{k,n})$ will be given in the subsequent sections, where they will be seen to be dependent on whether the underlying density f has heavy tail or light tail.

In the heavy-tailed density case, we take $E_k = ([-\infty, \infty]^d)^k \setminus \{\mathbf{0}\}$ and $d_{k,n} \equiv 0$. Thus there is no shift of the points X_i by $S(X_i)$, and all the scaling does is bring points closer to the origin. Consequently the point processes $N_n^{(k)}$ and $\tilde{N}_n^{(k)}$ asymptotically count geometric events equally likely in all the orthants.

On the other hand, in the case of light-tailed densities, one needs to take $E_k = ((-\infty, \infty]^d)^k$ and $d_{k,n}$ is generally non-zero. Since X_i is translated by $d_{k,n}S(X_i)$, this implies that, at least when n is large, $N_n^{(k)}$ and $\tilde{N}_n^{(k)}$ count geometric events basically only when they occur in the non-negative orthant. Nevertheless, the assumed spherical symmetry of the density allows our main results to be extended to general domains with only minor additional arguments.

Thus, since the aim of this section is to establish general theory on point process convergence, we shall leave this interpretative complication until it arises later in specific examples.

As remarked above, throughout the paper we take $k \geq 2$. Given the definitions above, we can now explain why this is the case. If $k = 1$, there is no shift invariant indicator to associate with the point process, and we have

$$N_n^{(1)}(\cdot) = \sum_{i=1}^{|\mathcal{P}_n|} \epsilon_{(c_{1,n}^{-1}(X_i - d_{1,n}S(X_i)), i/|\mathcal{P}_n|)}(\cdot).$$

This type of the point process has been well studied in classical EVT, and we have nothing to add about it.

We can now state the main result of this section. The proof is deferred to the Appendix.

THEOREM 2.1. *Let $(X_i, i \geq 1)$ be a sequence of i.i.d. $\mathbb{R}^d$ -valued spherically symmetric random variables. Let $h_n : (\mathbb{R}^d)^k \rightarrow \{0, 1\}$ be a sequence of indicators as in (2.8), satisfying shift invariance as in (2.6) and the points in proximity condition (2.7). Assume also that the vague convergence condition (2.17) and the sparsity condition (2.18) hold. Then*

$$N_n^{(k)} \Rightarrow N^{(k)},$$

where $\Rightarrow$ denotes weak convergence in the space $M_p(E_k \times L_k)$.

In addition, suppose that the global separation condition (2.19) holds. Then we also have that

$$\tilde{N}_n^{(k)} \Rightarrow N^{(k)}.$$

REMARK 2.2. *Note that the case $h \equiv 1$ is precluded by (2.7). In fact, if $h \equiv 1$, then it is easy to see that (2.17) and (2.18) cannot hold simultaneously.*

3. Heavy Tail Cases. As a special case of the general theory introduced in the last section, we shall discuss point process convergence when the underlying density on $\mathbb{R}^d$ has a heavy tail. More specifically, we assume that the density has a regularly varying tail (at infinity) in the sense that, for every $\theta \in S^{d-1}$ (equivalently, for some $\theta \in S^{d-1}$, due to the spherical symmetry of f), and some $\alpha > d$,

$$\lim_{r \rightarrow \infty} \frac{f(tr\theta)}{f(r\theta)} = t^{-\alpha}, \quad \text{for every } t > 0.$$

Writing $RV_{-\alpha}$ to denote the family of regularly varying functions (at infinity) of exponent $-\alpha$, then the above is equivalent to the requirement

$$(3.1) \quad f \in RV_{-\alpha}.$$

In the one-dimensional case ($d = 1$) it is known that regular variation of the tail in f suffices for the distribution to be in the max-domain of attraction of the Fréchet law; see for example Theorem 3.3.7 in [14].

In general, given a non-increasing sequence of positive numbers $(r_n, n \geq 1)$, we define h_n, g_n as in Section 2. Then, for a fixed positive integer $k \geq 2$, the point processes we are going to explore are

$$(3.2) \quad N_n^{(k)}(\cdot) = \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} h_n(\mathcal{X}_{\mathbf{i}}) \epsilon_{(R_{k,n}^{-1} \mathcal{X}_{\mathbf{i}}, \mathbf{i}/|\mathcal{P}_n|)}(\cdot),$$

and

$$(3.3) \quad \tilde{N}_n^{(k)}(\cdot) = \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) \epsilon_{(R_{k,n}^{-1} \mathcal{X}_{\mathbf{i}}, \mathbf{i}/|\mathcal{P}_n|)}(\cdot),$$

where $(R_{k,n}, n \geq 1)$ is asymptotically determined by

$$(3.4) \quad n^k r_n^{d(k-1)} R_{k,n}^d f(R_{k,n} e_1)^k \rightarrow 1 \quad \text{as } n \rightarrow \infty,$$

with $e_1 = (1, 0, \dots, 0)'$.

REMARK 3.1. *Note that (3.4) implicitly precludes very fast decay of r_n to zero. In fact, if $n^k r_n^{d(k-1)} \rightarrow 0$ as $n \rightarrow \infty$, then (3.4) implies that we must also have that $R_{k,n}^d f(R_{k,n} e_1)^k \rightarrow \infty$, which contradicts (3.1). However, under the implicit restriction that such rapid convergence does not occur, (3.4) effectively determines the $R_{k,n}$ as an intrinsic function of k and r_n .*

Note also that the case $r_n \equiv 1$ was the one treated in [1], although for a far more limited class of densities. In the case $r_n \equiv 1$, it is easy to check that $R_{k,n} \in RV_{(\alpha-d/k)-1}$ as a function of n .

The convergence in law of $N_n^{(k)}$ and $\tilde{N}_n^{(k)}$ takes place in the space $M_p(E_k \times L_k)$, where $E_k = ([-\infty, \infty]^d)^k \setminus \{\mathbf{0}\}$ and L_k is given in (2.14). Let $N^{(k)}$ be a limiting Poisson random measure, whose intensity is, as in Section 2, denoted by $\nu_k \times \lambda_k$, where λ_k is the k -dimensional Lebesgue measure concentrated on L_k . As a consequence of the heavy tail of f , the measure ν_k also exhibits a power-law tail structure. More specifically, for a rectangle $(a_0, b_0] \times \cdots \times (a_{k-1}, b_{k-1}] \subset E_k = ([-\infty, \infty]^d)^k \setminus \{\mathbf{0}\}$, which is bounded away from the origin,

$$(3.5) \quad \begin{aligned} & \nu_k((a_0, b_0] \times \cdots \times (a_{k-1}, b_{k-1}]) \\ &= \frac{1}{k!} \int_{(\mathbb{R}^d)^{k-1}} h(0, \mathbf{y}) d\mathbf{y} \int_{a_i \prec x \preceq b_i, i=0, \dots, k-1} \|x\|^{-\alpha k} dx \end{aligned}$$

where $\prec$ and $\preceq$ indicate componentwise inequalities.

It is worth mentioning that ν_k exhibits the scaling property:

$$(3.6) \quad \nu_k(sA) = s^{-(\alpha k - d)} \nu_k(A)$$

for all $s > 0$ and measurable A . We shall also need one additional function. For $\mathbf{x} = (x_1, \dots, x_k) \in (\mathbb{R}^d)^k$, $r > 0$, we define

$$(3.7) \quad p(\mathbf{x}; r) \triangleq \int_{\bigcup_{i=1}^k B(x_i; r)} f(z) dz.$$

We now have all we need to formulate the following result. The proof is given in the Appendix.

THEOREM 3.2. *Let $(X_i, i \geq 1)$ be a sequence of i.i.d. $\mathbb{R}^d$ -valued spherically symmetric random variables with density f having regularly varying tail as in (3.1). Let $h_n : (\mathbb{R}^d)^k \rightarrow \{0, 1\}$ be a sequence of indicators as in (2.8), satisfying the shift invariance of (2.6) and the points in proximity condition (2.7). Then, the point processes $N_n^{(k)}$ and $\tilde{N}_n^{(k)}$ given by (3.2) and (3.3) weakly converge to $N^{(k)}$ in the space $M_p(E_k \times L_k)$.*

To make the implications of the theorem a little more transparent, consider the simple case for which

$$(3.8) \quad f(x) = \frac{C}{1 + \|x\|^\alpha},$$

and assume that $r_n = n^s$ with $-k/d(k-1) < s \leq 0$. Then, (3.4) reduces to $n^{k+sd(k-1)} C^k R_{k,n}^{d-\alpha k} \rightarrow 1$ and solving this with respect to $R_{k,n}$ gives

$$R_{k,n} = C^{(\alpha-d/k)^{-1}} n^{[1+sd(1-k^{-1})]/(\alpha-d/k)},$$

FIG 3. Layer structure of annuli for random geometric graphs. For the density (3.8), $R_{k,n}$ is a regularly varying sequence with exponent $[1 + sd(1 - k^{-1})]/(\alpha - d/k)$. The number of subgraphs isomorphic to Γ_k outside $B(0; R_{k,n})$ is approximately Poisson.

which in turn implies $\dots \ll R_{k,n} \ll R_{k-1,n} \ll \dots \ll R_{2,n}$.

Being more specific on the geometric side, consider the geometric graph example of (2.4), where connected graphs Γ_k with k vertices are fixed for $k = 2, 3, \dots$. Then the theorem implies that $\mathbb{R}^d$ can be divided into annuli of increasing radii, and the Γ_k , $k = 2, 3, \dots$ are (asymptotically) distributed in these annuli in a very specific fashion. Letting $\text{Ann}(K, L)$ denote an annulus of outer radius L and inner radius K , we have (in an asymptotic sense)

- Inside $\text{Ann}(R_{2,n}, \infty)$, there are finitely many Γ_2 , but none of $\Gamma_3, \Gamma_4, \dots$.
- Inside $\text{Ann}(R_{3,n}, R_{2,n})$, there are infinitely many Γ_2 and finitely many Γ_3 , but none of $\Gamma_4, \Gamma_5, \dots$.

In general,

- Inside $\text{Ann}(R_{k,n}, R_{k-1,n})$, there are infinitely many $\Gamma_2, \dots, \Gamma_{k-1}$ and finitely many Γ_k , but none of $\Gamma_{k+1}, \Gamma_{k+2}, \dots$.

4. Light Tail Cases. This section treats point process convergence when the underlying density on $\mathbb{R}^d$ possesses a relatively lighter tail than in the previous section. Typically, in the spirit of extreme value theory, light-tailed densities can be formulated by the so-called von Mises function. In particular, in a one-dimensional case ($d = 1$), the von Mises function plays a decisive role in a characterisation of the max-domain of attraction of the Gumbel law. See Proposition 1.4 in [22]. The density formulation similar to our setup can be found, for example in [3] and [4].

Our results for the light tailed case fall into two categories. In the first, we have results more or less paralleling those of the previous section, although the normalisations and limiting distributions are somewhat different. Nevertheless, the ‘annuli structure’ in the preceding section carries through. This case is treated in Section 4.1. Recall, however, that in the heavy tail case these annuli are rather thick, especially when compared the typical size of the geometric objects, which is of order

r_n . In the light tail scenario, this is not the case, and the annuli are actually quite thin, which leads to questions that are not present in the heavy tail case. These questions are posed and solved in Section 4.2.

4.1. *Annuli.* The light tail case considers $(X_i, i \geq 1)$ of $\mathbb{R}^d$ -valued i.i.d. spherically symmetric random variables with density given by

$$(4.1) \quad f(x) = L(\|x\|) \exp\{-\psi(\|x\|)\}, \quad x \in \mathbb{R}^d.$$

Here, $\psi : \mathbb{R}_+ \rightarrow \mathbb{R}$ is a C^2 function of von Mises type, in that

$$\psi'(z) > 0, \quad \psi(z) \rightarrow \infty, \quad (1/\psi')'(z) \rightarrow 0$$

as $z \rightarrow z_\infty$, for some $z_\infty \in (0, \infty]$. The main objects of this paper are the geometric objects far away from the origin, so the bounded support of the density (i.e., $z_\infty < \infty$) is relatively less interesting to us. Therefore, in what follows, we restrict to the unbounded support case, in which $z_\infty = \infty$. For notational convenience, we introduce the function

$$a(z) = \frac{1}{\psi'(z)}.$$

Since $a'(z) \rightarrow 0$ as $z \rightarrow \infty$, the Cesàro mean of a' converges as well. That is,

$$\frac{a(z)}{z} = \frac{1}{z} \int_0^z a'(r) dr \rightarrow 0, \quad \text{as } z \rightarrow \infty.$$

Suppose that the function $L : \mathbb{R}_+ \rightarrow \mathbb{R}_+$ in (4.1) is *flat* for a ; viz.

$$(4.2) \quad \frac{L(t + a(t)v)}{L(t)} \rightarrow 1 \quad \text{as } t \rightarrow \infty \text{ uniformly on bounded } v\text{-sets.}$$

This assumption implies that L is negligible in its tail, and hence the tail behaviour of f is determined only by ψ . Here, we need to introduce an extra regularity condition on L . Assume that there exist $\gamma \geq 0$, $z_0 > 0$, and $C \geq 1$ such that

$$(4.3) \quad \frac{L(zt)}{L(z)} \leq C t^\gamma \quad \text{for all } t > 1, z \geq z_0.$$

In view of Corollary 2.0.5 in [7] (or Theorem 2.0.1 there),

$$(4.4) \quad \limsup_{z \rightarrow \infty} \frac{L(zt)}{L(z)} < \infty \quad \text{for all } t > 1$$

suffices for (4.3). Observe that if L is a polynomial function, then both (4.2) and (4.4) are satisfied. On the other hand, (4.4) does not hold if L grows exponentially.

Given a non-increasing sequence $(r_n, n \geq 1)$ of positive numbers (as usual constant r_n is permissible), we define h_n and g_n as in the previous sections. Suppose that there exists a non-decreasing sequence $(R_{k,n}, n \geq 1)$ determined by

$$(4.5) \quad n^k r_n^{d(k-1)} a(R_{k,n}) R_{k,n}^{d-1} f(R_{k,n} e_1)^k \rightarrow 1, \quad n \rightarrow \infty.$$

As pointed out in Remark 3.1, note that a rapid decay of (r_n) , e.g., $n^k r_n^{d(k-1)} \rightarrow 0$, $n \rightarrow \infty$ is not permissible. For $k \geq 2$, using abbreviations (2.10), (2.11), and (2.12), so that

$$c_{k,n} = a(R_{k,n}), \quad d_{k,n} = R_{k,n},$$

we shall consider the following point processes in the space $M_p(E_k \times L_k)$ with $E_k = ((-\infty, \infty]^d)^k$ and L_k given by (2.14):

$$(4.6) \quad N_n^{(k)}(\cdot) = \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} h_n(\mathcal{X}_{\mathbf{i}}) \epsilon_{(\mathcal{X}_{\mathbf{i}}^{(n)}, \mathbf{i}/|\mathcal{P}_n|)}(\cdot).$$

and

$$(4.7) \quad \tilde{N}_n^{(k)}(\cdot) = \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) \epsilon_{(\mathcal{X}_{\mathbf{i}}^{(n)}, \mathbf{i}/|\mathcal{P}_n|)}(\cdot),$$

As seen below in more detail, the nontriviality of weak limits of $N_n^{(k)}$ and $\tilde{N}_n^{(k)}$ mainly depends on the limit value of $a(R_{k,n})/r_n$. Indeed, if $a(R_{k,n})/r_n$ has a non-zero limit, then $N_n^{(k)}$ and $\tilde{N}_n^{(k)}$ both converge to the same Poisson random measure. On the contrary, if $a(R_{k,n})/r_n \rightarrow 0$, then $N_n^{(k)}$ goes to 0 in probability (and of course, so does $\tilde{N}_n^{(k)}$), which implies that the geometric objects implicit in h_n cannot be observed outside $B(0; R_{k,n})$, regardless of whether or not those objects are isolated from other points.

The following is the main limit theorem of this subsection. The proof is deferred to the Appendix.

THEOREM 4.1. *Let $(X_i, i \geq 1)$ be a sequence of i.i.d. $\mathbb{R}^d$ -valued spherically symmetric random variables with density f provided in (4.1). Let $h_n : (\mathbb{R}^d)^k \rightarrow \{0, 1\}$ be a sequence of indicators as in (2.8), satisfying the shift invariance of (2.6) and the points in proximity condition (2.7).*

(i) If $a(R_{k,n})/r_n \rightarrow c \in (0, \infty]$ as $n \rightarrow \infty$, then the point processes $N_n^{(k)}$ and $\tilde{N}_n^{(k)}$ given by (4.6) and (4.7) converge weakly to a Poisson random measure with intensity $\nu_k \times \lambda_k$. Here, λ_k is the k -dimensional Lebesgue measure concentrated on L_k , and the measure ν_k is given by

$$(4.8) \quad \nu_k((a_0, b_0] \times \cdots \times (a_{k-1}, b_{k-1}])$$

$$\begin{aligned}
&= \frac{1}{k!} \int_{(\mathbb{R}^d)^{k-1}} \int_{\theta \succeq 0} \int_0^\infty \mathbf{1}(a_0 \prec \rho \theta \preceq b_0) \\
&\quad \times \mathbf{1}\left(a_i \prec (\rho + c^{-1} \langle \theta, y_i \rangle) \theta \preceq b_i, \ i = 1, \dots, k-1\right) \\
&\quad \times \exp\left\{-k\rho - c^{-1} \sum_{i=1}^{k-1} \langle \theta, y_i \rangle\right\} h(0, \mathbf{y}) d\rho J(\theta) d\theta d\mathbf{y},
\end{aligned}$$

where $a_i, b_i, i = 0, \dots, k-1$ are d -dimensional real vectors with $-\infty \prec a_i \preceq b_i \preceq \infty$, and $J(\theta) = |\partial x / \partial \theta|$ is the Jacobian

$$(4.9) \quad J(\theta) = \sin^{k-2}(\theta_1) \sin^{k-3}(\theta_2) \dots \sin(\theta_{k-2}).$$

(ii) Suppose $a(R_{k,n})/r_n \rightarrow 0$ as $n \rightarrow \infty$ and a is eventually non-increasing (i.e., a is non-increasing on (x_0, ∞) for some large x_0). Then, the point processes $N_n^{(k)}$ and $\tilde{N}_n^{(k)}$ converge to 0 in probability.

As was the case in the heavy tailed scenario, Theorem 4.1 (i) again implies the layer structure of annuli at different radii $\dots \ll R_{k,n} \ll R_{k-1,n} \ll \dots \ll R_{2,n}$ in which different structures can be found. In the current case, however, this is not as immediate, since now the normalisation also involves a translation, the asymptotic effect of which is to count geometric events only when they occur in the nonnegative orthant.

Recall that we are particularly interested in the distribution of geometric events outside the ball $B(0; R_{k,n})$, $k = 2, 3, \dots$, and this is captured by

$$\sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) \mathbf{1}(\|X_{i_j}\| \geq R_{k,n}, \ j = 1, \dots, k).$$

However, by the spherical symmetry of the underlying density, along with the independence of the sample points, the weak limit of this quantity is the same as that of

$$2^d \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) \epsilon_{\mathcal{X}_{\mathbf{i}}^{(n)}} \left(([0, \infty]^d)^k \right),$$

the limit of which can be computed directly from Theorem 4.1 (i). In other words, the spherical symmetry of a density allows one to extend the basic result on the weak convergence occurring in the nonnegative orthant to that in all orthants. Consequently we can obtain the same qualitative separation of geometric events into distinct annuli that we saw in the heavy tailed case.

To see how this works, consider the simple example $f(x) = Ce^{-\|x\|^\tau/\tau}$, for some $0 < \tau \leq 1$, and take $r_n \equiv 1$. Then, $a(z) = z^{1-\tau}$ clearly has a non-zero limit as $z \rightarrow \infty$, and so Theorem 4.1 (i) applies. Then, (4.5) becomes

$$n^k R_{k,n}^{d-\tau} C^k e^{-kR_{k,n}^\tau/\tau} \rightarrow 1,$$

and the solution

$$(4.10) \quad R_{k,n} = (\tau \log n + k^{-1}(d - \tau) \log(\tau \log n) + \tau \log C)^{1/\tau}$$

grows only logarithmically in n , whereas the $R_{k,n}$ of the previous section exhibited, essentially, power law growth. Thus, the description inherent in Figure 3 remains unchanged, except for the change in the values of $R_{k,n}$.

REMARK 4.2. *In particular, if $a(R_{k,n})/r_n \rightarrow \infty$, the limiting intensity measure ν_k can be simplified to*

$$(4.11) \quad \begin{aligned} \nu_k((a_0, b_0] \times \cdots \times (a_{k-1}, b_{k-1}]) \\ = \frac{1}{k!} \int_{(\mathbb{R}^d)^{k-1}} h(0, \mathbf{y}) d\mathbf{y} \int \int_{a_i \prec \rho \theta \preceq b_i, i=0, \dots, k-1, \theta \succeq 0} e^{-k\rho} d\rho J(\theta) d\theta, \end{aligned}$$

where $a_i, b_i, i = 0, \dots, k-1$ are d -dimensional vectors such that $-\infty \prec a_i \preceq b_i \preceq \infty$.

REMARK 4.3. *In the case of $k = 1$, the point process $N_n^{(1)}$ is no longer associated with the indicator h_n and is given by*

$$N_n^{(1)}(\cdot) = \sum_{i=1}^{|\mathcal{P}_n|} \epsilon_{(a(R_{1,n})^{-1}(X_i - R_{1,n} S(X_i)), i/|\mathcal{P}_n|)}(\cdot).$$

Interestingly, a simpler argument than the proof of Theorem 4.1 (or combining standard arguments of point process theory – e.g. Chapters 5 and 6 of [23] – with the Palm theory in the Appendix) shows that regardless of whether $a(R_{1,n})$ has a zero or a non-zero limit, $N_n^{(1)}$ converges weakly to a Poisson random measure with a non-trivial intensity.

Before concluding this subsection, we look at several examples of light-tailed densities for which the corresponding point processes exhibit different limiting behaviours.

EXAMPLE 4.4. *Suppose, for simplicity, that $r_n \equiv 1$ and consider the following probability densities on $\mathbb{R}^d$:*

$$\begin{aligned} f_1(x) &= L_1(\|x\|) e^{-\|x\|^\tau}, \quad 0 < \tau < 1, \quad x \in \mathbb{R}^d, \\ f_2(x) &= L_2(\|x\|) e^{-\|x\| \log \log \|x\| / \log \|x\|}, \quad x \in \mathbb{R}^d, \end{aligned}$$

where the L_1 and L_2 satisfy (4.2) and (4.3). The densities f_1 and f_2 are usually referred to as subexponential densities, since their tails decay more slowly than

that of an exponential distribution. For both f_1 and f_2 , it is easy to check that $a(z) \rightarrow \infty$ as $z \rightarrow \infty$, so, by Theorem 4.1 (i), the point processes $N_n^{(k)}$ and $\tilde{N}_n^{(k)}$ weakly converge to a Poisson random measure with intensity $\nu_k \times \lambda_k$, where ν_k is given by (4.11). On the other hand, if the density has the same tail as an exponential distribution; for example,

$$f_3(x) = L_3(\|x\|)e^{-\|x\|}, \quad x \in \mathbb{R}^d,$$

then $\psi(z) = z$ and $a(z) = 1$. In this case, $N_n^{(k)}$ and $\tilde{N}_n^{(k)}$ once again weakly converge to a Poisson random measure. However, its intensity measure $\nu_k \times \lambda_k$ is more complicated, where ν_k is given by (4.8) with $c = 1$. We shall also consider the densities with more rapidly decaying tails than an exponential distribution (they are sometimes called superexponential densities). Two examples of superexponential densities are

$$\begin{aligned} f_4(x) &= L_4(\|x\|)e^{-\|x\|^\tau}, \quad \tau > 1, \quad x \in \mathbb{R}^d, \\ f_5(x) &= L_5(\|x\|)e^{-\|x\| \log \|x\| / \log \log \|x\|}, \quad x \in \mathbb{R}^d. \end{aligned}$$

For f_4 and f_5 , it follows that $a(z) \rightarrow 0$ as $z \rightarrow \infty$, and so Theorem 4.1 (ii) implies that the point process $N_n^{(k)}$ goes to 0 in probability. The densities f_2 , f_3 , and f_5 differ only slightly in their tail behaviours, but the corresponding point processes possess totally different limits. Finally, we point out that even for f_4 and f_5 , if one chooses $(r_n, n \geq 1)$ so that $a(R_{k,n})/r_n \rightarrow c \in (0, \infty]$, then the point process can converge to a non-trivial Poisson random measure.

4.2. At the annuli boundaries. The claim of Part (ii) of Theorem 4.1 is that, when $a(R_{k,n})/r_n \rightarrow 0$, the geometric objects being counted do not exist outside of the ball $B(0; R_{k,n})$, at least from the view of the point process convergence. We next want to explore the existence of the same objects inside $B(0; R_{k,n})$, under the condition that these objects must be isolated from other random points by at least r_n . This question was partially and negatively answered in [1], in the framework of the asymptotics of the expected Betti numbers of the Čech complexes associated with a random sample and a unit radius. In particular it was shown there that for the standard Gaussian distribution, all the expected Betti numbers of order $k \geq 1$ vanish and the resulting Čech complex becomes contractible. In what follows, we continue working on the same question under the conditions of Theorem 4.1 (ii) from a more comprehensive viewpoint.

Theorem 4.5 establishes the existence of two sequences of balls with different radii, the smaller ones ultimately containing so many points that they can be covered by a union of balls with radius r_n and centred on the points. On the other

hand, ultimately there are no points outside a larger balls. The main point, however, is that the differences between the radii of the two balls decays at the rate of $o(r_n)$. We conclude, therefore, that, at least when n is large, a union of balls with radius r_n centred at points in $\mathcal{P}_n$ becomes contractible, and accordingly, the geometric objects that we have been studying up until now, which are isolated from other points, fail to exist anywhere in all of $\mathbb{R}^d$.

In order to get a clear picture, we shall add extra assumptions to the setup of Theorem 4.1 (ii). In particular, we assume that

$$(4.12) \quad \psi \in RV_v \text{ for some } 1 < v < \infty,$$

$$(4.13) \quad L \equiv C \text{ (suitable normalising constant).}$$

and

$$(4.14) \quad (r_n) \text{ is a regularly varying sequence which decreases to 0 as } n \rightarrow \infty.$$

The reason why we need $v > 1$ in (4.12) is as follows. By Proposition 2.5 in [23], which establishes the regular variation of the derivative of a regularly varying function, we now have

$$a(z) = 1/\psi'(z) \in RV_{1-v}.$$

The setup of Theorem 4.1 (ii) requires that $a(z) \rightarrow 0$ as $z \rightarrow \infty$, so the regular variation exponent of ψ cannot be less than 1. Finally we observe that $\psi^{\leftarrow} \in RV_{1/v}$ and $a \circ \psi^{\leftarrow} \in RV_{(1-v)/v}$, and both functions are eventually monotone.

THEOREM 4.5. *Assume the conditions of Theorem 4.1 (ii), as well as (4.12), (4.13), and (4.14). Furthermore, assume that*

$$(4.15) \quad \frac{a \circ \psi^{\leftarrow}(\log n)}{r_n} \log \log n \rightarrow 0 \text{ as } n \rightarrow \infty.$$

Then, there exist two sequences $(R_n^{(0)}, n \geq 1)$ and $(R_n^{(1)}, n \geq 1)$ such that, as $n \rightarrow \infty$,

$$\mathbb{P} \left\{ B(0; R_n^{(0)}) \subset \bigcup_{X \in \mathcal{P}_n \cap B(0; R_n^{(0)})} B(X; r_n), \quad \mathcal{P}_n \cap B(0; R_n^{(1)})^c = \emptyset \right\} \rightarrow 1,$$

and

$$(4.16) \quad r_n^{-1} (R_n^{(1)} - R_n^{(0)}) \rightarrow 0.$$

FIG 4. Asymptotically, the smaller ball of radius $R_n^{(0)}$ is covered by a union of balls with radius r_n centred around the points in $\mathcal{P}_n$. There are no points outside a larger ball $R_n^{(1)}$. The difference between $R_n^{(1)}$ and $R_n^{(0)}$ vanishes at the rate of $o(r_n)$.

REMARK 4.6. Typically, the solution to (4.5) is given by $R_{k,n} = \psi^{\leftarrow}(\log n + b_{k,n})$, where $b_{k,n}/\log n \rightarrow 0$ as $n \rightarrow \infty$; (cf. (4.10).) Because of the regular variation of $a \circ \psi^{\leftarrow}$, the condition $a(R_{k,n})/r_n \rightarrow 0$ in Theorem 4.1 (ii) is equivalent to $a \circ \psi^{\leftarrow}(\log n)/r_n \rightarrow 0$. In essence, therefore, assuming (4.15) adds a stronger condition to Theorem 4.1 (ii). We have not been able to determine whether or not the same result can be obtained when $a \circ \psi^{\leftarrow}(\log n)/r_n \rightarrow 0$ holds but (4.15) is no longer true.

PROOF. First of all, we claim that $(r_n) \in RV_0$. To see this, note that it will suffice to show that $\log r_n / \log n \rightarrow 0$ as $n \rightarrow \infty$, since (r_n) is a regularly varying sequence. (cf. Proposition 2.6 (i) in [23].) Since $a \circ \psi^{\leftarrow} \in RV_{(1-v)/v}$, it is clear that $a \circ \psi^{\leftarrow}(\log n) \log n \rightarrow \infty$, and so,

$$\frac{\log r_n}{\log n} = \frac{a \circ \psi^{\leftarrow}(\log n)}{r_n} \frac{r_n \log r_n}{a \circ \psi^{\leftarrow}(\log n) \log n} \rightarrow 0, \quad n \rightarrow \infty.$$

For positive numbers g and ρ , let $\mathcal{Q}_n(g, \rho)$ be a family of cubes with grid gr_n that are contained in $B(0; \rho)$. Fix $g > 0$ sufficiently small so that

$$\{Q \cap \mathcal{P}_n \neq \emptyset \text{ for all } Q \in \mathcal{Q}_n(g, \rho)\} \subset \left\{ B(0; \rho) \subset \bigcup_{X \in \mathcal{P}_n \cap B(0; \rho)} B(X; r_n) \right\}$$

for all $\rho > 0$ and $n \geq 1$. We define $R_n^{(0)}$ and $R_n^{(1)}$ as follows:

$$R_n^{(0)} = \psi^{\leftarrow}(A_n), \quad A_n = \log n + d \log r_n - \log \log r_n^{-1} \psi^{\leftarrow}(\log n) - \delta,$$

where δ is a positive constant such that

$$(4.17) \quad d - e^\delta g^d C < 0,$$

and

$$R_n^{(1)} = \psi^{\leftarrow}(B_n),$$

where

$$B_n = \log n + (d-1) \log \psi^{\leftarrow}(\log n) + \log a \circ \psi^{\leftarrow}(\log n) + \log \log n.$$

We need to prove that, as $n \rightarrow \infty$,

$$(4.18) \quad \mathbb{P}\{Q \cap \mathcal{P}_n = \emptyset \text{ for some } Q \in \mathcal{Q}_n(g, R_n^{(0)})\} \rightarrow 0,$$

and

$$(4.19) \quad \mathbb{P}\{\mathcal{P}_n \cap B(0; R_n^{(1)})^c = \emptyset\} \rightarrow 1.$$

The probability in (4.18) is estimated from above by

$$(4.20) \quad \begin{aligned} \sum_{Q \in \mathcal{Q}_n(g, R_n^{(0)})} \mathbb{P}\{Q \cap \mathcal{P}_n = \emptyset\} &= \sum_{Q \in \mathcal{Q}_n(g, R_n^{(0)})} \exp\left\{-n \int_Q f(x) dx\right\} \\ &\leq \sum_{Q \in \mathcal{Q}_n(g, R_n^{(0)})} \exp\left\{-n (gr_n)^d f(R_n^{(0)} e_1)\right\} \\ &\leq \left(\frac{R_n^{(0)}}{gr_n}\right)^d \exp\left\{-g^d nr_n^d f(R_n^{(0)} e_1)\right\}. \end{aligned}$$

By virtue of the inequality $R_n^{(0)} \leq \psi^{\leftarrow}(\log n)$ and (4.17), we have, as $n \rightarrow \infty$,

$$d \log r_n^{-1} R_n^{(0)} - g^d nr_n^d f(R_n^{(0)} e_1) \leq (d - e^\delta g^d C) \log r_n^{-1} \psi^{\leftarrow}(\log n) \rightarrow -\infty$$

from which the rightmost term in (4.20) vanishes as $n \rightarrow \infty$.

Next, we turn to proving (4.19). Since

$$\mathbb{P}\{\mathcal{P}_n \cap B(0; R_n^{(1)})^c = \emptyset\} = \exp\left\{-n \int_{\|x\| \geq R_n^{(1)}} f(x) dx\right\},$$

it is enough to show $n \int_{\|x\| \geq R_n^{(1)}} f(x) dx \rightarrow 0$, as $n \rightarrow \infty$. By the polar coordinate transform with $J(\theta) = |\partial x / \partial \theta|$, we can write

$$\begin{aligned} n \int_{\|x\| \geq R_n^{(1)}} f(x) dx &= s_{d-1} n a(R_n^{(1)}) (R_n^{(1)})^{d-1} f(R_n^{(1)} e_1) \\ &\quad \times \int_0^\infty \left(1 + \frac{a(R_n^{(1)})}{R_n^{(1)}} \rho\right)^{d-1} \frac{f((R_n^{(1)} + a(R_n^{(1)}) \rho) e_1)}{f(R_n^{(1)} e_1)} d\rho, \end{aligned}$$

where s_{d-1} is a surface area of the $(d-1)$ -dimensional unit sphere in $\mathbb{R}^d$. The dominated convergence theorem guarantees that the integral above converges to $\int_0^\infty e^{-\rho} d\rho = 1$. Therefore, we only have to verify that

$$na(R_n^{(1)})(R_n^{(1)})^{d-1}e^{-\psi(R_n^{(1)})} \rightarrow 0, \quad \text{as } n \rightarrow \infty.$$

Substituting $R_n^{(1)} = \psi^{\leftarrow}(B_n)$, we have

$$na(R_n^{(1)})(R_n^{(1)})^{d-1}e^{-\psi(R_n^{(1)})} = \frac{a \circ \psi^{\leftarrow}(B_n)}{a \circ \psi^{\leftarrow}(\log n)} \left(\frac{\psi^{\leftarrow}(B_n)}{\psi^{\leftarrow}(\log n)} \right)^{d-1} (\log n)^{-1}.$$

Since $B_n/\log n \rightarrow 1$, it follows from the uniform convergence of regularly varying functions (cf. Proposition 2.4 in [23]) that

$$\frac{a \circ \psi^{\leftarrow}(B_n)}{a \circ \psi^{\leftarrow}(\log n)} \rightarrow 1, \quad \frac{\psi^{\leftarrow}(B_n)}{\psi^{\leftarrow}(\log n)} \rightarrow 1.$$

So the proof of (4.19) is complete.

It remains to establish (4.16). The mean value theorem yields

$$\begin{aligned} r_n^{-1}(R_n^{(1)} - R_n^{(0)}) &= r_n^{-1}(\psi^{\leftarrow})'(t_n)(B_n - A_n) \\ &= \frac{a \circ \psi^{\leftarrow}(t_n)}{a \circ \psi^{\leftarrow}(\log n)} \frac{a \circ \psi^{\leftarrow}(\log n)}{r_n} (B_n - A_n), \end{aligned}$$

where t_n lies in between A_n and B_n . Since $A_n/\log n \rightarrow 1$ and $B_n/\log n \rightarrow 1$, we have $t_n/\log n \rightarrow 1$, and thus,

$$\frac{a \circ \psi^{\leftarrow}(t_n)}{a \circ \psi^{\leftarrow}(\log n)} \rightarrow 1 \quad \text{as } n \rightarrow \infty.$$

To finish the argument, we have to establish the following three limits:

$$(4.21) \quad \frac{a \circ \psi^{\leftarrow}(\log n)}{r_n} \log r_n \rightarrow 0,$$

$$(4.22) \quad \frac{a \circ \psi^{\leftarrow}(\log n)}{r_n} \log a \circ \psi^{\leftarrow}(\log n) \rightarrow 0,$$

$$(4.23) \quad \frac{a \circ \psi^{\leftarrow}(\log n)}{r_n} \log \psi^{\leftarrow}(\log n) \rightarrow 0.$$

Since $\log a \circ \psi^{\leftarrow}(\log n) < \log r_n$ for sufficiently large n , (4.21) is implied by (4.22). By virtue of the regular variation of $a \circ \psi^{\leftarrow}$ and $\psi^{\leftarrow}$, we have that

$$\left(\frac{\log a \circ \psi^{\leftarrow}(\log n)}{\log \log n} \right) \quad \text{and} \quad \left(\frac{\log \psi^{\leftarrow}(\log n)}{\log \log n} \right)$$

are bounded sequences. Both (4.22) and (4.23) now follow from (4.15), and so we are done. $\square$

5. Applications.

5.1. *Limit Theorems for Betti Numbers.* The results of the previous two sections show the existence of a sequences of annuli containing different kinds of geometric objects. This subsection will further examine this layer structure and the topological properties of the objects they include, relying on the notion of Betti numbers to quantify the topology. Our aim is to derive limit theorems for the Betti numbers of the Čech complex built over $\mathcal{P}_n = \{X_1, \dots, X_{N_n}\}$, where $(X_i, i \geq 1)$ is an i.i.d sample drawn from a spherically symmetric distribution, and $N_n = |\mathcal{P}_n|$ is a Poisson random variable with mean n and is independent of $(X_i, i \geq 1)$. For $k \geq 3$, we take $h_n : (\mathbb{R}^d)^k \rightarrow \{0, 1\}$ as in (2.5); viz.

$$h_n(x_1, \dots, x_k) = \mathbf{1}\left(\beta_{k-2}\left(\check{C}(\{x_1, \dots, x_k\}, r_n)\right) = 1\right), \quad x_1, \dots, x_k \in \mathbb{R}^d,$$

and define $g_n : (\mathbb{R}^d)^k \rightarrow \{0, 1\}$ as in (2.9). Also, we define

$$\widehat{S}_{k,n} = \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|,k}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) \mathbf{1}(\|X_{i_j}\| \geq R_{k,n}, j = 1, \dots, k)$$

for $\mathcal{X}_{\mathbf{i}} = (X_{i_1}, \dots, X_{i_k})$ with $\mathbf{i} = (i_1, \dots, i_k) \in \mathcal{I}_{|\mathcal{P}_n|,k}$. The definition of $R_{k,n}$ depends on whether the underlying density has a heavy tail or a light tail. Specifically, if the underlying density has a regularly varying tail as in (3.1), then (3.4) defines the $R_{k,n}$, while (4.5) determines the $R_{k,n}$ if the density is given by (4.1). We are interested in the behaviour of the Betti numbers

$$\beta_{k-2}\left(\check{C}(\mathcal{P}_n \cap B(0; R_{k,n})^c, r_n)\right).$$

The most relevant study to this subsection is [1], in which the asymptotics of the expected Betti numbers were discussed. We, however, go well beyond this, by establishing Poisson limits for the Betti numbers. As originally given in [1], we shall provide one useful inequality to elucidate the relation between $\widehat{S}_{k,n}$ above and the Betti numbers:

$$\widehat{S}_{k,n} \leq \beta_{k-2}\left(\check{C}(\mathcal{P}_n \cap B(0; R_{k,n})^c, r_n)\right) \leq \widehat{S}_{k,n} + L_{k,n},$$

where

$$L_{k,n} = \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|,k+1}} \widetilde{h}_n(\mathcal{X}_{\mathbf{i}}) \mathbf{1}(\|X_{i_j}\| \geq R_{k,n}, j = 1, \dots, k+1),$$

with

$$\widetilde{h}_n(x_1, \dots, x_{k+1}) = \mathbf{1}\left(\check{C}(\{x_1, \dots, x_{k+1}\}, r_n) \text{ is connected}\right).$$

The limit theorem below demonstrates that $L_{k,n}$ tends to zero in probability, and as a result, $\widehat{S}_{k,n}$ and $\beta_{k-2}(\check{C}(\mathcal{P}_n \cap B(0; R_{k,n})^c, r_n))$ asymptotically coincide.

FIG 5. For $k = 3, d = 2$, the Betti number $\beta_1\left(\check{C}(\mathcal{P}_n \cap B(0; R_{3,n})^c, r_n)\right)$ counts (one-dimensional) cycles outside of $B(0; R_{3,n})$, while ignoring cycles inside the ball (e.g. (a), (b), and (c)).

THEOREM 5.1. Under the assumptions and notations of Theorem 3.2,

$$\beta_{k-2}\left(\check{C}(\mathcal{P}_n \cap B(0; R_{k,n})^c, r_n)\right) \Rightarrow Poi\left(\frac{s_{d-1}}{(\alpha k - d)k!} \int_{(\mathbb{R}^d)^{k-1}} h(0, \mathbf{y}) d\mathbf{y}\right)$$

where s_{d-1} is the surface area of the $(d - 1)$ -dimensional unit sphere in $\mathbb{R}^d$.

PROOF. First of all, note that the variable $\hat{S}_{k,n}$ defined above can also be written, in terms of the point process (3.3), as

$$\hat{S}_{k,n} = \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) \epsilon_{R_{k,n}^{-1} \mathcal{X}_{\mathbf{i}}} \left(\left\{ \mathbf{x} \in (\mathbb{R}^d)^k : \|x_i\| \geq 1, \ i = 1, \dots, k \right\} \right).$$

Appealing to Theorem 3.2,

$$\begin{aligned} \hat{S}_{k,n} &\Rightarrow Poi\left(\nu_k \left\{ \mathbf{x} \in (\mathbb{R}^d)^k : \|x_i\| \geq 1, \ i = 1, \dots, k \right\}\right) \\ &= Poi\left(\frac{s_{d-1}}{(\alpha k - d)k!} \int_{(\mathbb{R}^d)^{k-1}} h(0, \mathbf{y}) d\mathbf{y}\right) \quad \text{in } \mathbb{R}_+. \end{aligned}$$

If we can now show that $L_{k,n} \rightarrow 0$ in probability, then the previous line suffices to prove the theorem.

To this end, note that, in view of Theorem 3.2, the point process

$$(5.1) \quad \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k+1}} \tilde{h}_n(\mathcal{X}_{\mathbf{i}}) \epsilon_{R_{k+1,n}^{-1} \mathcal{X}_{\mathbf{i}}}(\cdot)$$

converges to a non-trivial Poisson random measure. Also, it is easy to see from (3.4) that $R_{k,n}/R_{k+1,n} \rightarrow \infty$ as $n \rightarrow \infty$. Therefore, replacing the scaling constants $R_{k+1,n}$ in (5.1) by $R_{k,n}$, the corresponding point process converges to zero in probability. Thus $L_{k,n} \xrightarrow{p} 0$ follows, as required. $\square$

THEOREM 5.2. *Assume the conditions of Theorem 4.1.*

(i) *If $a(R_{k,n})/r_n \rightarrow c \in (0, \infty]$ as $n \rightarrow \infty$, then*

$$\beta_{k-2}\left(\check{C}(\mathcal{P}_n \cap B(0; R_{k,n})^c, r_n)\right) \Rightarrow \text{Poi}\left(\frac{1}{k!} \int_{(\mathbb{R}^d)^{k-1}} \int_{S^{d-1}} \int_{\rho \geq 0, \rho+c^{-1}\langle \theta, y_i \rangle \geq 0, i=1, \dots, k-1} e^{-k\rho-c^{-1}\sum_{i=1}^{k-1}\langle \theta, y_i \rangle} h(0, \mathbf{y}) d\rho J(\theta) d\theta d\mathbf{y}\right).$$

(ii) *If $a(R_{k,n})/r_n \rightarrow 0$ as $n \rightarrow \infty$, then*

$$\beta_{k-2}\left(\check{C}(\mathcal{P}_n \cap B(0; R_{k,n})^c, r_n)\right) \xrightarrow{p} 0.$$

PROOF. For the proof of (i), note first that Theorem 4.1 (i), implies that

$$(5.2) \quad \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) \epsilon_{\mathcal{X}_{\mathbf{i}}^{(n)}}\left([0, \infty]^d\right)^k \Rightarrow \text{Poi}\left(\nu_k\left\{([0, \infty]^d)^k\right\}\right).$$

Due to the symmetry of the integral with respect to $\theta \in S^{d-1}$,

$$\begin{aligned} & \nu_k\left\{([0, \infty]^d)^k\right\} \\ &= \frac{1}{k!} \int_{(\mathbb{R}^d)^{k-1}} \int_{\theta \geq 0} \int_{\rho \geq 0, \rho+c^{-1}\langle \theta, y_i \rangle \geq 0, i=1, \dots, k-1} e^{-k\rho-c^{-1}\sum_{i=1}^{k-1}\langle \theta, y_i \rangle} h(0, \mathbf{y}) d\rho J(\theta) d\theta d\mathbf{y} \\ &= \frac{1}{2^d k!} \int_{(\mathbb{R}^d)^{k-1}} \int_{S^{d-1}} \int_{\rho \geq 0, \rho+c^{-1}\langle \theta, y_i \rangle \geq 0, i=1, \dots, k-1} e^{-k\rho-c^{-1}\sum_{i=1}^{k-1}\langle \theta, y_i \rangle} h(0, \mathbf{y}) d\rho J(\theta) d\theta d\mathbf{y}. \end{aligned}$$

Further, due to the spherical symmetry of the density, the left-hand side in (5.2) has the same weak limit as $2^{-d}\hat{S}_{k,n}$. Consequently, $\hat{S}_{k,n}$ weakly converges to

$$\text{Poi}\left(\frac{1}{k!} \int_{(\mathbb{R}^d)^{k-1}} \int_{S^{d-1}} \int_{\rho \geq 0, \rho+c^{-1}\langle \theta, y_i \rangle \geq 0, i=1, \dots, k-1} e^{-k\rho-c^{-1}\sum_{i=1}^{k-1}\langle \theta, y_i \rangle} h(0, \mathbf{y}) d\rho J(\theta) d\theta d\mathbf{y}\right).$$

To complete the proof of (i) it now suffices to verify that $L_{k,n} \rightarrow 0$ in probability as $n \rightarrow \infty$, which follows along the same lines as in the proof of Theorem 5.1.

To show (ii), note that

$$\beta_{k-2}\left(\check{C}(\mathcal{P}_n \cap B(0; R_{k,n})^c, r_n)\right)$$

$$\leq \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|,k}} h_n(\mathcal{X}_{\mathbf{i}}) \mathbf{1}(\|X_{i_j}\| \geq R_{k,n}, j = 1, \dots, k) + L_{k,n}.$$

The above expression has the same weak limit as

$$2^d \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|,k}} h_n(\mathcal{X}_{\mathbf{i}}) \epsilon_{\mathcal{X}_{\mathbf{i}}^{(n)}} \left(([0, \infty]^d)^k \right) + L_{k,n}.$$

Once again, $L_{k,n} \rightarrow 0$ in probability, and so the assertion follows from Theorem 4.1 (ii). $\square$

5.2. Limit Theorems for Partial Maxima. We now turn to describing the limiting behaviour of the maximum distance from the origin of the random points constituting the geometric objects that we have been studying so far. More specifically, we consider the ‘maxima process’

$$(5.3) \quad \bigvee_{\substack{1 \leq i_1 < \dots < i_k \leq |\mathcal{P}_n|t, \\ g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) = 1}} \frac{\|X_{i_1}\| - d_{k,n}}{c_{k,n}}, \quad t \in [0, 1],$$

where $a \vee b = \max\{a, b\}$ for $a, b \in \mathbb{R}$, and $c_{k,n} > 0$ and $d_{k,n} \in \mathbb{R}$ are the normalising sequences of the previous sections.

For a concrete example, suppose that $h_n : (\mathbb{R}^d)^k \rightarrow \{0, 1\}$ is defined as in (2.4), where Γ is a connected graph with k vertices. Then, a k -tuple of random points can contribute to the maxima process, only if its points serve as the vertices of graph isomorphic to Γ .

Note that the process (5.3) only requires the computation of the maximum of $\|X_{i_1}\|$ (suitably scaled and centred). However, in view of (2.7), all the components in $\mathcal{X}_{\mathbf{i}} = (X_{i_1}, \dots, X_{i_k})$ must be close to each other. Therefore, the results below will be robust as to which component is chosen from $\mathcal{X}_{\mathbf{i}}$.

We start with the regularly varying tail case, which is essentially a corollary of Theorem 3.2. The limit in this case is a *time-scaled extremal Fréchet process* (cf. [20]). The main difference between this and a classical extremal Fréchet process is that the former exhibits dependence in the max-increments, while the latter does not.

THEOREM 5.3. *Under the assumptions of Theorem 3.2, let (j_l, s_l) represent the points of a Poisson random measure with mean measure $\tilde{\nu}_k \times \tilde{\lambda}_k$, where $\tilde{\nu}_k(A) = \nu_k(A \times (\mathbb{R}^d)^{k-1})$ for a measurable set $A \subset \mathbb{R}^d$ (ν_k is defined in (3.5)), and $\tilde{\lambda}_k(B) = \lambda_k(\{(z_1, \dots, z_k) \in L_k, z_k \in B\})$ for measurable $B \subset [0, 1]$. Then,*

$$\bigvee_{\substack{1 \leq i_1 < \dots < i_k \leq |\mathcal{P}_n|t, \\ g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) = 1}} \frac{\|X_{i_1}\|}{R_{k,n}} \Rightarrow \bigvee_{s_l \leq t} \|j_l\|, \quad \text{in } D[0, 1],$$

where $D[0, 1]$ is the space of right continuous functions from $[0, 1]$ into $\mathbb{R}$ with left limits. The limiting process is a time-scaled extremal $(\alpha k - d)$ -Fréchet process with finite-dimensional laws determined as follows: for $0 = t_0 \leq t_1 < \dots < t_K \leq 1$, $\eta_i \geq 0$, $i = 1, \dots, K$,

(5.4)

$$\begin{aligned} & \mathbb{P}\left(\bigvee_{s_l \leq t_i} \|j_l\| \leq \eta_i, i = 1, \dots, K\right) \\ &= \exp\left\{-\frac{s_{d-1}}{(k!)^2(\alpha k - d)} \int_{(\mathbb{R}^d)^{k-1}} h(0, \mathbf{y}) d\mathbf{y} \sum_{i=1}^K (t_i^k - t_{i-1}^k) \left(\bigwedge_{i \leq j \leq K} \eta_j\right)^{-(\alpha k - d)}\right\}. \end{aligned}$$

PROOF. Restricting the domain of the point process convergence in Theorem 3.2, we have

$$\begin{aligned} & \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) \epsilon_{(R_{k,n}^{-1} X_{i_1}, i_k/|\mathcal{P}_n|)}(\cdot) \\ & \Rightarrow \sum_l \epsilon_{(j_l, s_l)}(\cdot) \text{ in } M_p\left([-\infty, \infty]^d \setminus \{0\}\right) \times [0, 1]. \end{aligned}$$

The functional $T : M_p\left([-\infty, \infty]^d \setminus \{0\}\right) \times [0, 1] \rightarrow D[0, 1]$ defined by $T(\sum_l \epsilon_{(z_l, \tau_l)}) = \bigvee_{\tau_l \leq \cdot} \|z_l\|$, is almost surely continuous. (cf. p214 of [22].) Applying the continuous mapping theorem immediately gives the required weak convergence.

What remains is to establish the precise form of the limit process, as in (5.4). To show this, note first that

$$\begin{aligned} & \mathbb{P}\left(\bigvee_{s_l \leq t_i} \|j_l\| \leq \eta_i, i = 1, \dots, K\right) \\ &= \exp\left\{-\sum_{i=1}^K \tilde{\nu}_k\left(\{z \in \mathbb{R}^d : \|z\| > \bigwedge_{i \leq j \leq K} \eta_j\}\right) \tilde{\lambda}_k((t_{i-1}, t_i])\right\}. \end{aligned}$$

By (3.5) and (3.6) we have that

$$\begin{aligned} & \tilde{\nu}_k\left(\{z \in \mathbb{R}^d : \|z\| > \bigwedge_{i \leq j \leq K} \eta_j\}\right) \\ &= \frac{s_{d-1}}{k!(\alpha k - d)} \int_{(\mathbb{R}^d)^{k-1}} h(0, \mathbf{y}) d\mathbf{y} \left(\bigwedge_{i \leq j \leq K} \eta_j\right)^{-(\alpha k - d)}, \end{aligned}$$

and

$$\tilde{\lambda}_k((t_{i-1}, t_i]) = (k!)^{-1}(t_i^k - t_{i-1}^k),$$

from which (5.4) now follows. $\square$

We now turn to the case of light-tailed densities. Note firstly that a similar, but simpler, argument than the proof of Theorems 2.1 and 4.1 shows that under the conditions in Theorem 4.1 (i), the point process

$$\sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) \epsilon \left(\left(a(R_{k,n})^{-1} (\|X_{i_j}\| - R_{k,n}), j=1, \dots, k \right), \mathbf{i}/|\mathcal{P}_n| \right) (\cdot)$$

converges weakly to a Poisson random measure with mean measure $\mu_k \times \lambda_k$. As usual, λ_k is the k -dimensional Lebesgue measure concentrated on L_k , and μ_k is given by

$$\begin{aligned} & \mu_k((a_0, b_0] \times \dots \times (a_{k-1}, b_{k-1}]) \\ &= \frac{1}{k!} \int_{(\mathbb{R}^d)^{k-1}} \int_{S_{d-1}} \int_{a_0}^{b_0} \mathbf{1}(a_i < \rho + c^{-1} \langle \theta, y_i \rangle \leq b_i, i = 1, \dots, k-1) \\ & \quad \times \exp \left\{ -k\rho - c^{-1} \sum_{i=1}^{k-1} \langle \theta, y_i \rangle \right\} h(0, \mathbf{y}) d\rho J(\theta) d\theta d\mathbf{y}, \end{aligned}$$

where $a_i, b_i, i = 0, \dots, k-1$ are one-dimensional real vectors with $-\infty < a_i \leq b_i \leq \infty$, and $J(\theta) = |\partial x / \partial \theta|$ is the Jacobian. Exploiting this result and mimicking the proof of Theorem 5.3, one can prove the following result, in which the limit is well described as a *time-scaled extremal Gumbel process*.

THEOREM 5.4. *Assume the conditions in Theorem 4.1, and let (j_l, s_l) be the points of a Poisson random measure with mean measure $\tilde{\mu}_k \times \tilde{\lambda}_k$, where $\tilde{\mu}_k(A) = \mu_k(A \times (\mathbb{R}^d)^{k-1})$ for a measurable set $A \subset \mathbb{R}$ and $\tilde{\lambda}_k(B) = \lambda_k(\{(z_1, \dots, z_k) \in L_k, z_k \in B\})$ for measurable $B \subset [0, 1]$.*

(i) *If $a(R_{k,n})/r_n \rightarrow c \in (0, \infty]$ as $n \rightarrow \infty$, then*

$$(5.5) \quad \bigvee_{\substack{1 \leq i_1 < \dots < i_k \leq |\mathcal{P}_n|t, \\ g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) = 1}} \frac{\|X_{i_1}\| - R_{k,n}}{a(R_{k,n})} \Rightarrow \bigvee_{s_l \leq t} j_l \text{ in } D[0, 1].$$

The finite dimensional laws of the limiting process are as follows: for $0 = t_0 \leq t_1 < \dots < t_K \leq 1, \eta_i \in \mathbb{R}, i = 1, \dots, K$,

$$\begin{aligned} & \mathbb{P} \left(\bigvee_{s_l \leq t_i} j_l \leq \eta_i, i = 1, \dots, K \right) \\ &= \exp \left\{ -\frac{1}{(k!)^2 k} \int_{(\mathbb{R}^d)^{k-1}} \int_{S_{d-1}} e^{-c^{-1} \sum_{i=1}^{k-1} \langle \theta, y_i \rangle} h(0, \mathbf{y}) J(\theta) d\theta d\mathbf{y} \right. \\ & \quad \left. \times \sum_{i=1}^K (t_i^k - t_{i-1}^k) e^{-k \wedge_{i \leq j \leq K} \eta_j} \right\}. \end{aligned}$$

(ii) If $a(R_{k,n})/r_n \rightarrow 0$ as $n \rightarrow \infty$, then the left-hand side in (5.5) converges to 0 in probability.

5.3. Limit Theorems for Partial Sums. Continuing on from the previous subsection, we now consider limit theorems on partial sums. In particular, we shall focus on a stable limit case. As seen in a variety of related studies such as [12] and [13], proving stable limit theorems via a point process approach has become the gold standard. In order to obtain stable limits, however, the underlying random variables constructing partial sums must have infinite second moments. For this reason, we shall assume a regularly varying tail for the underlying density, and further, that the homogeneity exponent $\alpha k - d$ in (3.6) lies in the interval $(0, 2)$. Combining this constraint with $\alpha > d$ and $k \geq 2$, we need to treat only the case $1 < \alpha < 1.5$, $k = 2$, and $d = 1$.

THEOREM 5.5. *Under the conditions of Theorem 3.2, assume that $1 < \alpha < 1.5$, $k = 2$, and $d = 1$. Suppose additionally that an indicator $h : \mathbb{R}^2 \rightarrow \{0, 1\}$ is not only shift invariant as in (2.6) but also symmetric in the sense that*

$$(5.6) \quad h(x_1, x_2) = h(-x_1, -x_2) \text{ for all } x_1, x_2 \in \mathbb{R}.$$

Then, $R_{2,n}^{-1} \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, 2}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) X_{i_1}$ converges weakly to a symmetric $(2\alpha - 1)$ -stable law.

PROOF. Restricting the domain of point process convergence shown in Theorem 3.2, we find that in the space $M_p([-\infty, \infty] \setminus \{0\})$,

$$\sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, 2}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) \epsilon_{R_{2,n}^{-1} X_{i_1}}(\cdot)$$

converges weakly to a Poisson random measure with intensity $\tilde{\nu}_2$, where $\tilde{\nu}_2(A) = \nu_2(A \times \mathbb{R})$ for measurable $A \subset \mathbb{R}$.

Under our parameter restrictions, the homogeneity exponent in (3.6) is $2\alpha - 1$, and thus the limiting Poisson random measure can be represented in law by

$$\sum_{j=1}^{\infty} \epsilon_{C_{\alpha} r_j \Gamma_j^{-(2\alpha-1)^{-1}}},$$

where $(r_j, j \geq 1)$ is a sequence of i.i.d. Rademacher random variables taking $+1$ and -1 with probability $1/2$, Γ_j is the j -th jump time of a unit rate Poisson process, and

$$C_{\alpha} = \left(\frac{1}{2\alpha - 1} \int_{\mathbb{R}} h(0, y) dy \right)^{1/(2\alpha-1)}.$$

Here, (r_j) and (Γ_j) are taken to be independent. Notice that due to its symmetry, $C_\alpha \sum_{j=1}^{\infty} r_j \Gamma_j^{-(2\alpha-1)^{-1}}$ converges almost surely and has a symmetric $(2\alpha - 1)$ -stable distribution. For more information about series representation of stable laws, see Section 1.4 of [25]. It is known that, for every $\delta > 0$, the functional $T_\delta : M_p([-\infty, \infty] \setminus \{0\}) \rightarrow \mathbb{R}$ defined by

$$T_\delta\left(\sum_l \epsilon_{z_l}\right) = \sum_l z_l \mathbf{1}(|z_l| > \delta)$$

is almost surely continuous. (cf. Section 7.2.3 in [23].) Applying the continuous mapping theorem, we have, as $n \rightarrow \infty$,

$$\begin{aligned} R_{2,n}^{-1} \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|,2}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) X_{i_1} \mathbf{1}(|X_{i_1}| > R_{2,n}\delta) \\ \Rightarrow C_\alpha \sum_{j=1}^{\infty} r_j \Gamma_j^{-(2\alpha-1)^{-1}} \mathbf{1}(C_\alpha \Gamma_j^{-(2\alpha-1)^{-1}} > \delta). \end{aligned}$$

As $\delta \downarrow 0$, we have

$$C_\alpha \sum_{j=1}^{\infty} r_j \Gamma_j^{-(2\alpha-1)^{-1}} \mathbf{1}(C_\alpha \Gamma_j^{-(2\alpha-1)^{-1}} > \delta) \Rightarrow C_\alpha \sum_{j=1}^{\infty} r_j \Gamma_j^{-(2\alpha-1)^{-1}}.$$

Hence, it remains to show that, for every $\eta > 0$,

$$\lim_{\delta \downarrow 0} \limsup_{n \rightarrow \infty} \mathbb{P}\left\{ \left| \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|,2}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) X_{i_1} \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta) \right| > \eta R_{2,n} \right\} = 0$$

However, by the Cauchy-Schwarz inequality, this will follow immediately if we can show that

$$(5.7) \quad \lim_{\delta \downarrow 0} \limsup_{n \rightarrow \infty} R_{2,n}^{-2} \mathbb{E}\left\{ \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|,2}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) X_{i_1} \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta) \right\}^2 = 0.$$

We can write

$$\begin{aligned} R_{2,n}^{-2} \mathbb{E}\left\{ \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|,2}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) X_{i_1} \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta) \right\}^2 \\ = R_{2,n}^{-2} \sum_{m=2}^{\infty} \mathbb{P}\{|\mathcal{P}_n| = m\} \mathbb{E}\left\{ \sum_{\mathbf{i} \in \mathcal{I}_{m,2}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{X}_m) X_{i_1} \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta) \right\}^2, \end{aligned}$$

where $\mathcal{X}_m = \{X_1, \dots, X_m\}$ for $m \geq 2$.

Now introduce a triangular array of i.i.d. Rademacher variables $(r_i, 1 \leq i_1 < i_2 < \infty)$, which are independent of $(X_i, i \geq 1)$. Then, by virtue of the symmetry of the X_i , it follows that, for all $n \geq 1$ and $m \geq 2$,

$$\begin{aligned} & \left(g_n(\mathcal{X}_i, \mathcal{X}_m) X_{i_1} \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta), \mathbf{i} \in \mathcal{I}_{m,k} \right) \\ & \stackrel{d}{=} \left(g_n(r_i \mathcal{X}_i, r_i \mathcal{X}_m) r_i X_{i_1} \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta), \mathbf{i} \in \mathcal{I}_{m,k} \right). \end{aligned}$$

We now observe that

$$\begin{aligned} & \mathbb{E} \left\{ \sum_{\mathbf{i} \in \mathcal{I}_{m,2}} g_n(\mathcal{X}_i, \mathcal{X}_m) X_{i_1} \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta) \right\}^2 \\ & = \mathbb{E} \left\{ \sum_{\mathbf{i} \in \mathcal{I}_{m,2}} g_n(r_i \mathcal{X}_i, r_i \mathcal{X}_m) r_i X_{i_1} \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta) \right\}^2 \\ & = \sum_{\mathbf{i} \in \mathcal{I}_{m,2}} \sum_{\mathbf{j} \in \mathcal{I}_{m,2}} \mathbb{E} \left\{ X_{i_1} X_{j_1} \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta, |X_{j_1}| \leq R_{2,n}\delta) \right. \\ & \quad \left. \times \mathbb{E} \left\{ r_i r_j g_n(r_i \mathcal{X}_i, r_i \mathcal{X}_m) g_n(r_j \mathcal{X}_j, r_j \mathcal{X}_m) \mid \mathcal{X}_m \right\} \right\} \end{aligned}$$

If $\mathbf{i} \neq \mathbf{j}$, r_i and r_j are independent, and so

$$\begin{aligned} & \mathbb{E} \left\{ r_i r_j g_n(r_i \mathcal{X}_i, r_i \mathcal{X}_m) g_n(r_j \mathcal{X}_j, r_j \mathcal{X}_m) \mid \mathcal{X}_m \right\} \\ & = \mathbb{E} \left\{ r_i g_n(r_i \mathcal{X}_i, r_i \mathcal{X}_m) \mid \mathcal{X}_m \right\} \mathbb{E} \left\{ r_j g_n(r_j \mathcal{X}_j, r_j \mathcal{X}_m) \mid \mathcal{X}_m \right\} \\ & = 4^{-1} \left(g_n(\mathcal{X}_i, \mathcal{X}_m) - g_n(-\mathcal{X}_i, -\mathcal{X}_m) \right) \left(g_n(\mathcal{X}_j, \mathcal{X}_m) - g_n(-\mathcal{X}_j, -\mathcal{X}_m) \right) \\ & = 0, \end{aligned}$$

where the last equality follows from (5.6).

This implies that all cross terms will vanish, and so

$$\begin{aligned} & \mathbb{E} \left\{ \sum_{\mathbf{i} \in \mathcal{I}_{m,2}} g_n(\mathcal{X}_i, \mathcal{X}_m) X_{i_1} \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta) \right\}^2 \\ & = \sum_{\mathbf{i} \in \mathcal{I}_{m,2}} \mathbb{E} \left\{ g_n(r_i \mathcal{X}_i, r_i \mathcal{X}_m) X_{i_1}^2 \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta) \right\} \\ & = \sum_{\mathbf{i} \in \mathcal{I}_{m,2}} \mathbb{E} \left\{ g_n(\mathcal{X}_i, \mathcal{X}_m) X_{i_1}^2 \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta) \right\} \\ & \leq \binom{m}{2} \mathbb{E} \left\{ h_n(X_1, X_2) X_1^2 \mathbf{1}(|X_1| \leq R_{2,n}\delta) \right\}. \end{aligned}$$

Finally, we have that

$$\begin{aligned}
& R_{2,n}^{-2} \mathbb{E} \left\{ \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|,2}} g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) X_{i_1} \mathbf{1}(|X_{i_1}| \leq R_{2,n}\delta) \right\}^2 \\
& \leq R_{2,n}^{-2} \sum_{m=2}^{\infty} \mathbb{P}\{|\mathcal{P}_n| = m\} \binom{m}{2} \mathbb{E} \left\{ h_n(X_1, X_2) X_1^2 \mathbf{1}(|X_1| \leq R_{2,n}\delta) \right\} \\
& = \frac{n^2}{2R_{2,n}^2} \int_{\mathbb{R}^2} h_n(x_1, x_2) x_1^2 \mathbf{1}(|x_1| \leq R_{2,n}\delta) f(x_1) f(x_2) dx_1 dx_2 \\
& = \frac{n^2 r_n}{R_{2,n}^2} \int_0^{R_{2,n}\delta} x^2 f(x) \int_{\mathbb{R}} f(x|1 + r_n y/x|) h(0, y) dy dx \\
& \leq \frac{n^2 r_n}{R_{2,n}^2} \int_0^{R_{2,n}\delta} x^2 f(x)^2 \int_{\mathbb{R}} \sup_{m \geq 1} \frac{f(x|1 + r_m y/x|)}{f(x)} h(0, y) dy dx.
\end{aligned}$$

Here, the equality in the fourth line is obtained by the change of variables $x_1 \leftrightarrow x$, $x_2 \leftrightarrow x + r_n y$. Since (r_n) is a bounded sequence, it follows from the uniform convergence of regularly varying functions of negative exponent (cf. Proposition 2.4 in [23]) that

$$\sup_{m \geq 1} \frac{f(x|1 + r_m y/x|)}{f(x)} \rightarrow 1, \quad \text{as } x \rightarrow \infty,$$

uniformly in $y \in \mathbb{R}$ with $h(0, y) = 1$.

Thus, as $x \rightarrow \infty$,

$$U(x) \equiv \int_{\mathbb{R}} \sup_{m \geq 1} \frac{f(x|1 + r_m y/x|)}{f(x)} h(0, y) dy \rightarrow \int_{\mathbb{R}} h(0, y) dy \in (0, \infty).$$

This fact implies that $x^2 f(x)^2 U(x)$ is regularly varying with exponent $2 - 2\alpha$. By an application of Karamata's theorem (e.g. Theorem 2.1 in [23]),

$$\begin{aligned}
\frac{n^2 r_n}{R_{2,n}^2} \int_0^{R_{2,n}\delta} x^2 f(x)^2 U(x) dx & \sim \frac{n^2 r_n}{3 - 2\alpha} R_{2,n} \delta^3 f(R_{2,n}\delta)^2 U(R_{2,n}\delta) \\
& \sim n^2 r_n R_{2,n} f(R_{2,n})^2 \frac{\delta^{3-2\alpha}}{3 - 2\alpha} \int_{\mathbb{R}} h(0, y) dy \\
& \rightarrow \frac{\delta^{3-2\alpha}}{3 - 2\alpha} \int_{\mathbb{R}} h(0, y) dy \quad \text{as } n \rightarrow \infty.
\end{aligned}$$

Since $\delta^{3-2\alpha} \rightarrow 0$ as $\delta \downarrow 0$, (5.7) follows. $\square$

6. Appendix.

6.1. *Proof of Theorem 2.1.* For the completion of Theorem 2.1, we need several important ingredients, all of which belong to the ‘Palm theory’ of Poisson point processes. They are useful when computing expectations related to Poisson point processes. We recall abbreviations (2.1), (2.2), together with (2.3).

LEMMA 6.1. (*Palm theory for Poisson point processes*, [2]; see also Theorem 1.6 in [21]) Let $(X_i, i \geq 1)$ be i.i.d. $\mathbb{R}^d$ -valued random variables with common density f , and for $n \geq 1$, let $\mathcal{P}_n$ denote a Poisson point process with intensity nf . Let $u_n(\mathcal{Y}, \mathcal{X})$ be a measurable function defined for $\mathcal{Y} = (y_1, \dots, y_k)$, $y_i \in \mathbb{R}^d$ and a finite subset $\mathcal{X} \supset \mathcal{Y}$ of d -dimensional real vectors. Then,

$$\mathbb{E} \left\{ \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} u_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) \right\} = \frac{n^k}{k!} \mathbb{E} \{ u_n(\mathcal{X}_k, \mathcal{X}_k \cup \mathcal{P}'_n) \},$$

where $\mathcal{P}'_n$ is an independent copy of $\mathcal{P}_n$.

LEMMA 6.2. Under the same notation as Lemma 6.1, let $u_n(\mathcal{Y})$ be a measurable function defined for $\mathcal{Y} = (y_1, \dots, y_k)$, $y_i \in \mathbb{R}^d$. Let λ_k be the k -dimensional Lebesgue measure concentrated on the upper diagonal part of the unit cube; viz. $L_k = \{(z_1, \dots, z_k) \in [0, 1]^k : 0 \leq z_1 \leq \dots \leq z_k \leq 1\}$. Then, for a measurable set $B \subset L_k$,

$$\mathbb{E} \left\{ \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} u_n(\mathcal{X}_{\mathbf{i}}) \mathbf{1}(\mathbf{i}/|\mathcal{P}_n| \in B) \right\} \sim \frac{n^k}{k!} \mathbb{E} \{ u_n(\mathcal{X}_k) \} \lambda_k(B), \quad \text{as } n \rightarrow \infty.$$

PROOF.

$$\begin{aligned} & \mathbb{E} \left\{ \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} u_n(\mathcal{X}_{\mathbf{i}}) \mathbf{1}(\mathbf{i}/|\mathcal{P}_n| \in B) \right\} \\ &= \sum_{m=k}^{\infty} \mathbb{P}\{|\mathcal{P}_n| = m\} \mathbb{E} \left\{ \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} u_n(\mathcal{X}_{\mathbf{i}}) \mathbf{1}(\mathbf{i}/|\mathcal{P}_n| \in B) \mid |\mathcal{P}_n| = m \right\} \\ &= \frac{n^k}{k!} \mathbb{E} \{ u_n(\mathcal{X}_k) \} \sum_{m=k}^{\infty} e^{-n} \frac{n^{m-k}}{(m-k)!} \binom{m}{k}^{-1} \# \{ \mathbf{i} \in \mathcal{I}_{m,k} \cap mB \}. \end{aligned}$$

The proof then follows from the fact that

$$\binom{m}{k}^{-1} \# \{ \mathbf{i} \in \mathcal{I}_{m,k} \cap mB \} \rightarrow \lambda_k(B) \quad \text{as } m \rightarrow \infty.$$

□

LEMMA 6.3. *Under the same notation as Lemma 6.1, let $u_n(\mathcal{Y})$ be a non-negative measurable function defined for all finite subsets $\mathcal{Y} = (y_1, \dots, y_k)$, $y_i \in \mathbb{R}^d$. Suppose further that $n^k \mathbb{E} u_n(\mathcal{X}_k) \rightarrow C$, $n \rightarrow \infty$ for some constant $C > 0$. Then, for a measurable set $B \subset L_k$,*

$$\mathbb{E} \left| \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} u_n(\mathcal{X}_{\mathbf{i}}) \mathbf{1}(\mathbf{i}/|\mathcal{P}_n| \in B) - \sum_{\mathbf{i} \in \mathcal{I}_{n, k}} u_n(\mathcal{X}_{\mathbf{i}}) \mathbf{1}(\mathbf{i}/n \in B) \right| \rightarrow 0, \quad n \rightarrow \infty.$$

PROOF. We can proceed as follows.

$$\begin{aligned} & \mathbb{E} \left| \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} u_n(\mathcal{X}_{\mathbf{i}}) \mathbf{1}(\mathbf{i}/|\mathcal{P}_n| \in B) - \sum_{\mathbf{i} \in \mathcal{I}_{n, k}} u_n(\mathcal{X}_{\mathbf{i}}) \mathbf{1}(\mathbf{i}/n \in B) \right| \\ &= \sum_{m=0}^{\infty} \mathbb{P}\{|\mathcal{P}_n| = m\} \left| \#\{\mathbf{i} \in \mathcal{I}_{m, k} \cap mB\} - \#\{\mathbf{i} \in \mathcal{I}_{n, k} \cap nB\} \right| \mathbb{E}\{u_n(\mathcal{X}_k)\} \\ &\sim C n^{-k} \sum_{m=0}^{\infty} \mathbb{P}\{|\mathcal{P}_n| = m\} \left| \#\{\mathbf{i} \in \mathcal{I}_{n, k} \cap nB\} - \#\{\mathbf{i} \in \mathcal{I}_{m, k} \cap mB\} \right| \\ &\leq C n^{-k} \sum_{m=0}^{\infty} \mathbb{P}\{|\mathcal{P}_n| = m\} \left| \#\{\mathbf{i} \in \mathcal{I}_{n, k} \cap nB\} - \frac{n^k}{k!} \lambda_k(B) \right| \\ &\quad + C n^{-k} \sum_{m=0}^{\infty} \mathbb{P}\{|\mathcal{P}_n| = m\} |n^k - m^k| \frac{\lambda_k(B)}{k!} \\ &\quad + C n^{-k} \sum_{m=0}^{\infty} \mathbb{P}\{|\mathcal{P}_n| = m\} \left| \frac{m^k}{k!} \lambda_k(B) - \#\{\mathbf{i} \in \mathcal{I}_{m, k} \cap mB\} \right| \\ &\equiv J_1 + J_2 + J_3. \end{aligned}$$

Evidently, $J_1 \rightarrow 0$ as $n \rightarrow \infty$. It is also easy to check that

$$J_2 = C \frac{\lambda_k(B)}{k!} \mathbb{E} \left| \left(\frac{|\mathcal{P}_n|}{n} \right)^k - 1 \right| \rightarrow 0 \quad \text{as } n \rightarrow \infty.$$

As for J_3 , given $\epsilon > 0$, there is an integer $N \geq 1$ such that

$$\left| \frac{k!}{m^k} \#\{\mathbf{i} \in \mathcal{I}_{m, k} \cap mB\} - \lambda_k(B) \right| < \epsilon \quad \text{for all } m \geq N.$$

Then, there exists a constant $C' \geq C$ such that for all $m \geq N$,

$$J_3 \leq C' n^{-k} \sum_{m=0}^{N-1} \mathbb{P}\{|\mathcal{P}_n| = m\} \frac{m^k}{k!} + C \epsilon n^{-k} \sum_{m=N}^{\infty} \mathbb{P}\{|\mathcal{P}_n| = m\} \frac{m^k}{k!}$$

Obviously, the first term on the right-hand side vanishes. The second term is bounded by $C\epsilon(k!)^{-1}n^{-k}\mathbb{E}|\mathcal{P}_n|^k$. Since $\sup_{n \geq 1} n^{-k}\mathbb{E}|\mathcal{P}_n|^k < \infty$ and ϵ is arbitrary, we conclude that $J_1 + J_2 + J_3 \rightarrow 0$ as $n \rightarrow \infty$. $\square$

Before starting the proof of Theorem 2.1, we note that we shall often use, without further comment, the fact that, for every $k \geq 1$,

$$\binom{n}{k} \sim \frac{n^k}{k!},$$

in the sense that the ratio of the two sides tends to 1 as $n \rightarrow \infty$.

PROOF OF THEOREM 2.1. For the convergence of $N_n^{(k)}$, according to Kallenberg's theorem (see Proposition 3.22 in [22]), it suffices to show that

$$(6.1) \quad \mathbb{E} \left\{ N_n^{(k)}(R) \right\} \rightarrow \mathbb{E} \left\{ N^{(k)}(R) \right\},$$

and

$$(6.2) \quad \mathbb{P} \left\{ N_n^{(k)}(R) = 0 \right\} \rightarrow \mathbb{P} \left\{ N^{(k)}(R) = 0 \right\},$$

for every disjoint union of measurable sets of the form $R = \bigcup_{p=1}^m (A_p \times B_p)$, where A_p is relatively compact in E_k with $\nu_k(\partial A_p) = 0$ (i.e. the boundary of A_p has ν_k -measure 0), and B_p is a measurable set in L_k .

For the proof of (6.1), we can set, without loss of generality, $m = 1$, and write $A = A_1$, $B = B_1$. By virtue of Lemma 6.2 in the Appendix, together with (2.17),

$$\begin{aligned} \mathbb{E} \left\{ N_n^{(k)}(A \times B) \right\} &\sim \frac{n^k}{k!} \mathbb{P} \left\{ h_n(\mathcal{X}_k) = 1, \mathcal{X}_k^{(n)} \in A \right\} \lambda_k(B) \\ &\rightarrow \nu_k(A) \lambda_k(B) = \mathbb{E} \left\{ N^{(k)}(A \times B) \right\}. \end{aligned}$$

Now we proceed to (6.2). Setting

$$\xi_{\mathbf{i},n} = h_n(\mathcal{X}_{\mathbf{i}}) \epsilon_{(\mathcal{X}_{\mathbf{i}}^{(n)}, \mathbf{i}/n)}(R), \quad \mathbf{i} = \{i_1, \dots, i_k\} \in \mathcal{I}_{n,k},$$

we see that

$$\begin{aligned} &\left| \mathbb{P} \left\{ N_n^{(k)}(R) = 0 \right\} - \mathbb{P} \left\{ N^{(k)}(R) = 0 \right\} \right| \\ &\leq \left| \mathbb{P} \left\{ N_n^{(k)}(R) = 0 \right\} - \mathbb{P} \left\{ \sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \xi_{\mathbf{i},n} = 0 \right\} \right| \\ &\quad + \left| \mathbb{P} \left\{ \sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \xi_{\mathbf{i},n} = 0 \right\} - \mathbb{P} \left\{ N^{(k)}(R) = 0 \right\} \right| \equiv I_1 + I_2. \end{aligned}$$

We recall the following basic inequality: for integer-valued random variables X and Y defined on the same probability space,

$$|\mathbb{P}\{X = 0\} - \mathbb{P}\{Y = 0\}| \leq \mathbb{E}|X - Y|.$$

Combining this inequality and Lemma 6.3 in the Appendix proves $I_1 \rightarrow 0$ as $n \rightarrow \infty$. To demonstrate that $I_2 \rightarrow 0$ as $n \rightarrow \infty$, we introduce the total variation distance: for real-valued random variables X and Y defined on the same probability space $(\Omega, \mathcal{F}, \mathbb{P})$,

$$d_{\text{TV}}(X, Y) \equiv \sup_{A \in \mathcal{F}} |\mathbb{P}\{X \in A\} - \mathbb{P}\{Y \in A\}|.$$

Using this norm,

$$\begin{aligned} (6.3) \quad & \left| \mathbb{P}\left\{ \sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \xi_{\mathbf{i},n} = 0 \right\} - \mathbb{P}\{N^{(k)}(R) = 0\} \right| \\ & \leq d_{\text{TV}}\left(\sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \xi_{\mathbf{i},n}, \text{Poi}\left(\mathbb{E}\left\{ \sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \xi_{\mathbf{i},n} \right\}\right) \right) \\ & \quad + d_{\text{TV}}\left(\text{Poi}\left(\mathbb{E}\left\{ \sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \xi_{\mathbf{i},n} \right\}\right), N^{(k)}(R) \right). \end{aligned}$$

Since the total variation distance between two Poisson variables can be bounded by the difference of their means (see Lemma 7.3 in [8]), we have

$$d_{\text{TV}}\left(\text{Poi}\left(\mathbb{E}\left\{ \sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \xi_{\mathbf{i},n} \right\}\right), N^{(k)}(R) \right) \leq \left| \mathbb{E}\left\{ \sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \xi_{\mathbf{i},n} \right\} - \mathbb{E}\{N^{(k)}(R)\} \right|.$$

Thus the final term in (6.3) converges to zero as $n \rightarrow \infty$.

To handle the first term on the right hand side of (6.3), note first that each $\xi_{\mathbf{i},n}$ is a Bernoulli random variable. To handle dependencies, create a graph with vertices the indices $\mathbf{i} \in \mathcal{I}_{n,k}$ by placing an edge between $\mathbf{i}$ and $\mathbf{j}$ (write $\mathbf{i} \sim \mathbf{j}$) if $\mathbf{i}$ and $\mathbf{j}$ share at least one component (i.e. if $|\mathbf{i} \cap \mathbf{j}| > 0$). Then, $(\mathcal{I}_{n,k}, \sim)$ provides a *dependency graph* with respect to $(\xi_{\mathbf{i},n}, \mathbf{i} \in \mathcal{I}_{n,k})$; that is, for any two disjoint subsets I_1, I_2 of $\mathcal{I}_{n,k}$ with no edges connecting I_1 and I_2 , $(\xi_{\mathbf{i},n}, \mathbf{i} \in I_1)$ is independent of $(\xi_{\mathbf{i},n}, \mathbf{i} \in I_2)$. Therefore, we are able to apply the so-called Poisson approximation theorem (see [2] and also, Theorem 2.1 in [21]):

$$d_{\text{TV}}\left(\sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \xi_{\mathbf{i},n}, \text{Poi}\left(\mathbb{E}\left\{ \sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \xi_{\mathbf{i},n} \right\}\right) \right)$$

$$\leq 3 \left\{ \sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \sum_{\mathbf{j} \in N_{\mathbf{i}}} \mathbb{E}\{\xi_{\mathbf{i},n}\} \mathbb{E}\{\xi_{\mathbf{j},n}\} + \sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \sum_{\mathbf{j} \in N_{\mathbf{i}} \setminus \{\mathbf{i}\}} \mathbb{E}\{\xi_{\mathbf{i},n} \xi_{\mathbf{j},n}\} \right\},$$

where $N_{\mathbf{i}} = \{\mathbf{j} \in \mathcal{I}_{n,k} : |\mathbf{i} \cap \mathbf{j}| > 0\}$. Now, for large enough n ,

$$\mathbb{E}\{\xi_{\mathbf{i},n}\} \leq \sum_{p=1}^m \mathbb{P}\{h_n(\mathcal{X}_k) = 1, \mathcal{X}_k^{(n)} \in A_p\} \leq 2 \binom{n}{k}^{-1} \sum_{p=1}^m \nu_k(A_p),$$

and thus

$$\sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \sum_{\mathbf{j} \in N_{\mathbf{i}}} \mathbb{E}\{\xi_{\mathbf{i},n}\} \mathbb{E}\{\xi_{\mathbf{j},n}\} \leq \binom{n}{k} \left(\binom{n}{k} - \binom{n-k}{k} \right) 4 \binom{n}{k}^{-2} \left(\sum_{p=1}^m \nu_k(A_p) \right)^2.$$

Here, it is clear that the right-hand side vanishes as $n \rightarrow \infty$.

For $\mathbf{i}, \mathbf{j} \in \mathcal{I}_{n,k}$ with $|\mathbf{i} \cap \mathbf{j}| = l \in \{1, \dots, k-1\}$,

$$\begin{aligned} \mathbb{E}\{\xi_{\mathbf{i},n} \xi_{\mathbf{j},n}\} &\leq \sum_{p=1}^m \sum_{p'=1}^m \mathbb{P} \left\{ h_n(\mathcal{X}_k) = 1, \mathcal{X}_k^{(n)} \in A_p, \right. \\ &\quad \left. h_n(X_1, \dots, X_l, X_{k+1}, \dots, X_{2k-l}) = 1, \right. \\ &\quad \left. (c_{k,n}^{-1}(X_j - d_{k,n} S(X_j)), j = 1, \dots, l, k+1, \dots, 2k-l) \in A_{p'} \right\}. \end{aligned}$$

Regardless of the definition of E_k , there exists a compact set $K_1 \subset E_{2k-l}$ such that for all $p, p' = 1, \dots, m$,

$$\begin{aligned} \{(x_1, \dots, x_{2k-l}) \in (\mathbb{R}^d)^{2k-l} : (x_1, \dots, x_k) \in A_p, \\ (x_1, \dots, x_l, x_{k+1}, \dots, x_{2k-l}) \in A_{p'}\} \subset K_1 \end{aligned}$$

Thus, for some constant $C_1 > 0$,

$$\begin{aligned} &\sum_{\mathbf{i} \in \mathcal{I}_{n,k}} \sum_{\mathbf{j} \in N_{\mathbf{i}} \setminus \{\mathbf{i}\}} \mathbb{E}\{\xi_{\mathbf{i},n} \xi_{\mathbf{j},n}\} \\ &= \sum_{l=1}^{k-1} \binom{n}{k} \binom{k}{l} \binom{n-k}{k-l} \mathbb{E}\{\xi_{\mathbf{i},n} \xi_{\mathbf{j},n}\} \mathbf{1}(|\mathbf{i} \cap \mathbf{j}| = l) \\ &\leq C_1 \sum_{l=1}^{k-1} n^{2k-l} \mathbb{P} \left\{ h_n(\mathcal{X}_k) = 1, h_n(X_1, \dots, X_l, X_{k+1}, \dots, X_{2k-l}) = 1, \right. \\ &\quad \left. \mathcal{X}_{2k-l}^{(n)} \in K_1 \right\} \rightarrow 0 \text{ as } n \rightarrow \infty, \end{aligned}$$

where the last convergence follows from (2.18) and now, (6.2) is proved as required.

In order to prove that $\tilde{N}_n^{(k)}$ has the same weak limit as $N_n^{(k)}$, we only have to verify that for every non-negative continuous function $f : E_k \times L_k \rightarrow \mathbb{R}_+$ with compact support,

$$\begin{aligned} N_n^{(k)}(f) - \tilde{N}_n^{(k)}(f) \\ = \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} (h_n(\mathcal{X}_{\mathbf{i}}) - g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n)) f(\mathcal{X}_{\mathbf{i}}^{(n)}, \mathbf{i}/|\mathcal{P}_n|) \xrightarrow{P} 0. \end{aligned}$$

Let K_2 be a compact set in E_k so that the support of f is contained in $K_2 \times L_k$. Noting that $\|f\|_\infty = \sup_{(x,y) \in K_2 \times L_k} f(x,y) < \infty$,

$$\begin{aligned} N_n^{(k)}(f) - \tilde{N}_n^{(k)}(f) \\ \leq \|f\|_\infty \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} \mathbf{1} \left(h_n(\mathcal{X}_{\mathbf{i}}) = 1, g_n(\mathcal{X}_{\mathbf{i}}, \mathcal{P}_n) = 0, \mathcal{X}_{\mathbf{i}}^{(n)} \in K_2 \right). \end{aligned}$$

In view of the Palm theory in Lemma 6.1 in the Appendix, we need to show that

$$n^k \mathbb{P} \{ h_n(\mathcal{X}_k) = 1, g_n(\mathcal{X}_k, \mathcal{X}_k \cup \mathcal{P}'_n) = 0, \mathcal{X}_k^{(n)} \in K_2 \} \rightarrow 0,$$

where $\mathcal{P}'_n$ is an independent copy of $\mathcal{P}_n$. Combining (2.17) and (2.19) completes the proof. $\square$

6.2. Proof of Theorem 3.2.

PROOF OF THEOREM 3.2. By Theorem 2.1, we only establish that the three convergence conditions, (2.17), (2.18), and (2.19), with $c_{k,n}$, $d_{k,n}$ replaced by $R_{k,n}$ and 0, respectively, are satisfied. Since the proof of (2.17) is very similar to (and actually even easier than) that of (2.19), we only check (2.18) and (2.19). We shall start with (2.19). In view of the Portmanteau theorem for vague convergence (e.g. Proposition 3.12 in [22]) we need to show

$$(6.4) \quad \binom{n}{k} \mathbb{P} \{ g_n(\mathcal{X}_k, \mathcal{X}_k \cup \mathcal{P}'_n) = 1, R_{k,n}^{-1} \mathcal{X}_k \in K \} \xrightarrow{v} \nu_k(K)$$

for all relatively compact K in $E_k = ([-\infty, \infty]^d)^k \setminus \{\mathbf{0}\}$ for which $\nu_k(\partial K) = 0$. Without loss of generality, we can take $K = (a_0, b_0] \times \cdots \times (a_{k-1}, b_{k-1}] \subset E_k$, where $a_i, b_i, i = 0, \dots, k-1$ are d -dimensional real vectors. Recall that any relatively compact set in E_k is bounded away from the origin, and as assumed in (2.7), $h(x_1, \dots, x_k) = 1$ only when $x_1, \dots, x_k$ are all close enough to each other.

Therefore, we can and shall assume that each $(a_i, b_i]$ is bounded away from the origin. In particular, we assume that there exists an $\eta > 0$ such that

$$(6.5) \quad (a_i, b_i] \subset \{x \in \mathbb{R}^d : \|x\| \geq \eta\}, \quad i = 0, \dots, k-1.$$

Consequently, we have

$$\begin{aligned} & \binom{n}{k} \mathbb{P}\{g_n(\mathcal{X}_k, \mathcal{X}_k \cup \mathcal{P}'_n) = 1, a_{i-1} \prec R_{k,n}^{-1} X_i \preceq b_{i-1}, i = 1, \dots, k\} \\ &= \binom{n}{k} \mathbb{E}\left\{h_n(\mathcal{X}_k) \mathbf{1}\left(a_{i-1} \prec R_{k,n}^{-1} X_i \preceq b_{i-1}, i = 1, \dots, k\right) \right. \\ &\quad \left. \times \mathbb{P}\left\{G(\mathcal{X}_k, r_n) \text{ is an isolated component of } G(\mathcal{X}_k \cup \mathcal{P}'_n, r_n) \mid \mathcal{X}_k\right\}\right\} \\ &= \binom{n}{k} \int_{(\mathbb{R}^d)^k} h_n(x_1, \dots, x_k) \mathbf{1}(a_{i-1} \prec R_{k,n}^{-1} x_i \preceq b_{i-1}, i = 1, \dots, k) \\ &\quad \times \exp\{-np(x_1, \dots, x_k; r_n)\} f(x_1) \dots f(x_k) d\mathbf{x}. \end{aligned}$$

Let I_k denote the last integral. The change of variables $x_1 \leftrightarrow x$, $x_i \leftrightarrow x + r_n y_{i-1}$, $i = 2, \dots, k$, together with the location invariance of h , yields

$$\begin{aligned} I_k &= \binom{n}{k} r_n^{d(k-1)} \int_{a_0 \prec R_{k,n}^{-1} x \preceq b_0} f(x) \int_{(\mathbb{R}^d)^{k-1}} h(0, \mathbf{y}) \prod_{i=1}^{k-1} \mathbf{1}(a_i \prec R_{k,n}^{-1}(x + r_n y_i) \preceq b_i) \\ &\quad \times f(x + r_n y_i) \exp\{-np(x, x + r_n \mathbf{y}; r_n)\} d\mathbf{y} dx. \end{aligned}$$

Applying the polar coordinate transform $x \leftrightarrow (r, \theta)$ with $J(\theta) = |\partial x / \partial \theta|$, and changing variables by setting $\rho = r / R_{k,n}$, gives

$$\begin{aligned} I_k &= \binom{n}{k} r_n^{d(k-1)} R_{k,n}^d f(R_{k,n} e_1)^k \\ &\quad \times \int_{(\mathbb{R}^d)^{k-1}} \int_{S^{d-1}} \int_0^\infty \mathbf{1}(a_0 \prec \rho \theta \preceq b_0) \rho^{d-1} f(R_{k,n} e_1)^{-1} f(R_{k,n} \rho e_1) \\ &\quad \times \prod_{i=1}^{k-1} \mathbf{1}(a_i \prec \rho \theta + r_n y_i / R_{k,n} \preceq b_i) f(R_{k,n} e_1)^{-1} f(R_{k,n} \|\rho \theta + r_n y_i / R_{k,n}\| e_1) \\ &\quad \times \exp\{-np(R_{k,n} \rho \theta, R_{k,n} \rho \theta + r_n \mathbf{y}; r_n)\} h(0, \mathbf{y}) d\rho J(\theta) d\theta d\mathbf{y}, \end{aligned}$$

where $J(\theta) = |\partial x / \partial \theta|$ is the usual Jacobian and S^{d-1} denotes the $(d-1)$ -dimensional unit sphere in $\mathbb{R}^d$. Recalling (3.4) and the assumption that f has a regularly varying tail of exponent $-\alpha$, we see that for all $\rho > 0$, $\theta \in S^{d-1}$ and

$$y_i \in \mathbb{R}^d, i = 1, \dots, k-1,$$

(6.6)

$$\begin{aligned} & \binom{n}{k} r_n^{d(k-1)} R_{k,n}^d f(R_{k,n} e_1)^k \frac{f(R_{k,n} \rho e_1)}{f(R_{k,n} e_1)} \prod_{i=1}^{k-1} \mathbf{1}(a_i \prec \rho\theta + r_n y_i / R_{k,n} \preceq b_i) \\ & \times \frac{f(R_{k,n} \|\rho\theta + r_n y_i / R_{k,n}\| e_1)}{f(R_{k,n} e_1)} \\ & \rightarrow \frac{1}{k!} \rho^{-\alpha k} \prod_{i=1}^{k-1} \mathbf{1}(a_i \prec \rho\theta \preceq b_i), \quad \text{as } n \rightarrow \infty. \end{aligned}$$

Subsequently, we shall show that

$$(6.7) \quad np(R_{k,n} \rho\theta, R_{k,n} \rho\theta + r_n \mathbf{y}; r_n) \rightarrow 0, \quad n \rightarrow \infty$$

for every $\rho > 0$, $\theta \in S^{d-1}$ and $y_i \in \mathbb{R}^d$, $i = 1, \dots, k-1$. By the change of variables,

(6.8)

$$\begin{aligned} & np(R_{k,n} \rho\theta, R_{k,n} \rho\theta + r_n \mathbf{y}; r_n) \\ & = nr_n^d f(R_{k,n} e_1) \int_{B(0;2) \cup \bigcup_{i=1}^{k-1} B(y_i;2)} f(R_{k,n} e_1)^{-1} f(R_{k,n} \|\rho\theta + r_n z / R_{k,n}\| e_1) dz. \end{aligned}$$

Appealing to the Potter bound (e.g. Theorem 1.5.6 in [7]), for every $\xi \in (0, \alpha)$, there is $C_1 > 0$ such that for sufficiently large n ,

$$\begin{aligned} & \sup_{z \in B(0;2) \cup \bigcup_{i=1}^{k-1} B(y_i;2)} \frac{f(R_{k,n} \|\rho\theta + r_n z / R_{k,n}\| e_1)}{f(R_{k,n} e_1)} \\ & \leq C_1 \sup_{z \in B(0;2) \cup \bigcup_{i=1}^{k-1} B(y_i;2)} \left(\|\rho\theta + r_n z / R_{k,n}\|^{-(\alpha+\xi)} + \|\rho\theta + r_n z / R_{k,n}\|^{-(\alpha-\xi)} \right) \\ & \leq C_1 (2\rho^{-(\alpha+\xi)} + 2\rho^{-(\alpha-\xi)}). \end{aligned}$$

Therefore, the supremum over n of the integral in (6.8) is finite. On the other hand, (3.4) ensures that $nr_n^d f(R_{k,n} e_1) \rightarrow 0$ as $n \rightarrow \infty$ and hence, the convergence in (6.7) follows.

Note that

$$\frac{1}{k!} \int_{(\mathbb{R}^d)^{k-1}} \int_{S^{d-1}} \int_0^\infty \rho^{d-1-\alpha k} \prod_{i=0}^{k-1} \mathbf{1}(a_i \prec \rho\theta \preceq b_i) h(0, \mathbf{y}) d\rho J(\theta) d\theta d\mathbf{y}$$

$$\begin{aligned}
&= \frac{1}{k!} \int_{(\mathbb{R}^d)^{k-1}} h(0, \mathbf{y}) d\mathbf{y} \int_{a_i \prec x \preceq b_i, i=0, \dots, k-1} \|x\|^{-\alpha k} dx \\
&= \nu_k((a_0, b_0] \times \dots \times (a_{k-1}, b_{k-1}]) .
\end{aligned}$$

Thus, the proof of (6.4) can be finished, provided that the convergence in (6.6) holds under the integral sign. Indeed, one more application of the Potter bound, together with (6.5), verifies the following: for every $\xi \in (0, \alpha - d)$, there exist $C_2, C_3 > 0$ such that

$$\mathbf{1}(a_0 \prec \rho\theta \preceq b_0) \frac{f(R_{k,n}\rho e_1)}{f(R_{k,n}e_1)} \leq C_2 \mathbf{1}(\rho \geq \eta) (\rho^{-(\alpha+\xi)} + \rho^{-(\alpha-\xi)}),$$

and

$$\begin{aligned}
&\prod_{i=1}^{k-1} \mathbf{1}(a_i \prec \rho\theta + r_n y_i / R_{k,n} \preceq b_i) \frac{f(R_{k,n} \|\rho\theta + r_n y_i / R_{k,n}\| e_1)}{f(R_{k,n} e_1)} \\
&\leq C_3 (\eta^{-(\alpha+\xi)(k-1)} + \eta^{-(\alpha-\xi)(k-1)}).
\end{aligned}$$

Since $\int_{\eta}^{\infty} (\rho^{d-1-\alpha+\xi} + \rho^{d-1-\alpha-\xi}) d\rho < \infty$, the dominated convergence theorem justifies the convergence under the integral sign, and so we have completed the first part of the proof; viz. (2.19) is satisfied.

Next, we shall prove (2.18). For $l = 1, \dots, k-1$ and every compact set $K \subset E_{2k-l} = ([-\infty, \infty]^d)^{2k-l} \setminus \{\mathbf{0}\}$, we can assume without loss of generality that there exists $\eta' > 0$ such that

$$K \subset \{(x_1, \dots, x_{2k-l}) \in (\mathbb{R}^d)^{2k-l} : \|x_i\| \geq \eta', i = 1, \dots, 2k-l\}.$$

Proceeding in the same manner as above, the probability in (2.18) is bounded by

$$\begin{aligned}
&n^{2k-l} \mathbb{P} \left\{ h_n(\mathcal{X}_k) = 1, h_n(X_1, \dots, X_l, X_{k+1}, \dots, X_{2k-l}) = 1, \right. \\
&\quad \left. \|X_i\| \geq \eta' R_{k,n}, i = 1, \dots, 2k-l \right\} \\
&= n^{2k-l} r_n^{d(2k-l-1)} R_{k,n}^d f(R_{k,n} e_1)^{2k-l} \\
&\quad \times \int_{(\mathbb{R}^d)^{2k-l-1}} \int_{S^{d-1}} \int_{\eta'}^{\infty} \rho^{d-1} f(R_{k,n} e_1)^{-1} f(R_{k,n} \rho e_1) \\
&\quad \times \prod_{i=1}^{2k-l-1} \mathbf{1}(\|\rho\theta + r_n y_i / R_{k,n}\| > \eta') f(R_{k,n} e_1)^{-1} f(R_{k,n} \|\rho\theta + r_n y_i / R_{k,n}\| e_1) \\
&\quad \times h(0, y_1, \dots, y_{k-1}) h(0, y_1, \dots, y_{l-1}, y_k, \dots, y_{2k-l-1}) d\rho J(\theta) d\theta d\mathbf{y}.
\end{aligned}$$

The asymptotic order of the last integral is $\mathcal{O}(n^{2k-l} r_n^{d(2k-l-1)} R_{k,n}^d f(R_{k,n} e_1)^{2k-l})$, which tends to 0 as $n \rightarrow \infty$ for every $l = 1, \dots, k-1$, and so we are done. $\square$

6.3. *Proof of Theorem 4.1.* For the proof of Theorem 4.1, we need a preliminary lemma.

LEMMA 6.4. (Lemma 5.2 in [3]) Given $(R_{k,n}, n \geq 1)$ as in (4.5), let $(q_m(n), m \geq 0, n \geq 1)$ be defined by

$$q_m(n) = a(R_{k,n})^{-1} \left(\psi^{\leftarrow}(\psi(R_{k,n}) + m) - R_{k,n} \right),$$

equivalently,

$$\psi(R_{k,n} + a(R_{k,n})q_m(n)) = \psi(R_{k,n}) + m$$

(since ψ is an increasing function, the inverse function $\psi^{\leftarrow}$ is well-defined everywhere). Then, given $\epsilon > 0$, there is an integer $N_\epsilon \geq 1$ such that

$$q_m(n) \leq e^{m\epsilon}/\epsilon \text{ for all } n \geq N_\epsilon, m \geq 0.$$

PROOF OF THEOREM 4.1. The proof is rather long, and so we break into two main units, one each for the two main cases, further dividing the proof of the first case into three sign-posted parts. Hopefully this will help the reader to navigate the next few pages.

Proof of statement (i)

Part 1: As argued in the proof of Theorem 3.2, we need only check (2.18) and (2.19). As for (2.19), we need to show that

$$(6.9) \quad \binom{n}{k} \mathbb{P}\{g_n(\mathcal{X}_k, \mathcal{X}_k \cup \mathcal{P}'_n) = 1, \mathcal{X}_k^{(n)} \in K\} \rightarrow \nu_k(K)$$

for all relatively compact K in $E_k = ((-\infty, \infty]^d)^k$ for which $\nu_k(\partial K) = 0$. Without loss of generality, it suffices to check the case $K = I_0 \times \cdots \times I_{k-1}$, where $I_i = (a_i, b_i] \subset \mathbb{R}^d$ and a_i, b_i are d -dimensional vectors such that $-\infty \prec a_i \preceq b_i \preceq \infty$. Define

$$H = S^{d-1} \cap \{(z_1, \dots, z_d) \in \mathbb{R}^d : z_1 + \cdots + z_d \geq 0\},$$

and let $H^c = S^{d-1} \setminus H$. Let $\Theta_1 = X_1/\|X_1\|$. Since $a(R_{k,n})^{-1}R_{k,n}S(X_1) \rightarrow \infty$ a.s. (in a componentwise sense), we have that, for large enough n , $\Theta_1 \in H^c$ and $a(R_{k,n})^{-1}(X_1 - R_{k,n}S(X_1)) \succeq a_0(\succ -\infty)$ do not occur simultaneously. Thus, the left-hand side in (6.9) equals

$$\binom{n}{k} \mathbb{P}\left\{g_n(\mathcal{X}_k, \mathcal{X}_k \cup \mathcal{P}'_n) = 1, \Theta_1 \in H, \mathcal{X}_k^{(n)} \in \prod_{i=1}^k I_{i-1}\right\} + o(1)$$

as $n \rightarrow \infty$. Letting J_k denote the leading term in the above, we can write

$$\begin{aligned} J_k &= \binom{n}{k} \mathbb{E} \left\{ h_n(\mathcal{X}_k) \mathbf{1} \left(\mathcal{X}_k^{(n)} \in \prod_{i=1}^k I_{i-1}, \Theta_1 \in H \right) \right. \\ &\quad \times \mathbb{P} \left\{ G(\mathcal{X}_k, r_n) \text{ is an isolated component of } G(\mathcal{X}_k \cup \mathcal{P}'_n, r_n) \mid \mathcal{X}_k \right\} \Big\} \\ &= \binom{n}{k} \int_{(\mathbb{R}^d)^k} h_n(x_1, \dots, x_k) \\ &\quad \times \mathbf{1} \left(a(R_{k,n})^{-1}(x_i - R_{k,n}S(x_i)) \in I_{i-1}, i = 1, \dots, k, x_1/\|x_1\| \in H \right) \\ &\quad \times \exp\{-np(x_1, \dots, x_k; r_n)\} f(x_1) \dots f(x_k) d\mathbf{x}, \end{aligned}$$

where the definition of p was given in (3.7).

The change of variables $x_1 \leftrightarrow x$ and $x_i \leftrightarrow x + r_n y_{i-1}$, $i = 2, \dots, k$ yields

$$\begin{aligned} J_k &= \binom{n}{k} r_n^{d(k-1)} \int_{\mathbb{R}^d} \mathbf{1} \left(a(R_{k,n})^{-1}(x - R_{k,n}S(x)) \in I_0, x/\|x\| \in H \right) f(x) \\ &\quad \times \int_{(\mathbb{R}^d)^{k-1}} h(0, \mathbf{y}) \prod_{i=1}^{k-1} \mathbf{1} \left(a(R_{k,n})^{-1}(x + r_n y_i - R_{k,n}S(x + r_n y_i)) \in I_i \right) \\ &\quad \times f(x + r_n y_i) \exp\{-np(x, x + r_n \mathbf{y}; r_n)\} d\mathbf{y} dx. \end{aligned}$$

Further calculation by the polar coordinate transform $x \leftrightarrow (r, \theta)$ with $J(\theta) = |\partial x / \partial \theta|$ and the change of variable $\rho = a(R_{k,n})^{-1}(r - R_{k,n})$ gives

$$\begin{aligned} J_k &= \binom{n}{k} r_n^{d(k-1)} a(R_{k,n}) R_{k,n}^{d-1} f(R_{k,n} e_1)^k \\ &\quad \times \int_{(\mathbb{R}^d)^{k-1}} \int_{S^{d-1}} \int_0^\infty \prod_{i=1}^6 L_i h(0, \mathbf{y}) d\rho J(\theta) d\theta d\mathbf{y}, \end{aligned}$$

where

$$\begin{aligned} L_1 &= \mathbf{1}(\rho\theta - a(R_{k,n})^{-1}R_{k,n}(S(\theta) - \theta) \in I_0, \theta \in H), \\ L_2 &= \left(1 + \frac{a(R_{k,n})}{R_{k,n}} \rho \right)^{d-1}, \\ L_3 &= f(R_{k,n}e_1)^{-1} f\left((R_{k,n} + a(R_{k,n})\rho)e_1\right), \\ L_4 &= \prod_{i=1}^{k-1} \mathbf{1}\left(\rho\theta + \frac{r_n}{a(R_{k,n})} y_i \right. \end{aligned}$$

$$\begin{aligned}
& -\frac{R_{k,n}}{a(R_{k,n})} \left[S\left((R_{k,n} + a(R_{k,n})\rho)\theta + r_n y_i\right) - \theta \right] \in I_i \Big), \\
L_5 &= \prod_{i=1}^{k-1} f(R_{k,n} e_1)^{-1} f\left(\|(R_{k,n} + a(R_{k,n})\rho)\theta + r_n y_i\| e_1\right), \\
L_6 &= \exp\left\{-np\left((R_{k,n} + a(R_{k,n})\rho)\theta, (R_{k,n} + a(R_{k,n})\rho)\theta + r_n \mathbf{y}; r_n\right)\right\}.
\end{aligned}$$

Part 2: For the application of the dominated convergence theorem, one needs to compute the limit for each L_i , $i = 1, \dots, 6$, while also establishing finite upper bounds for each term. We shall begin with the indicators L_1 and L_4 , which are trivially bounded. The fact that $a(R_{k,n})^{-1} R_{k,n} \rightarrow \infty$ ensures that

$$L_1 \rightarrow \mathbf{1}(\rho\theta \in I_0, \theta \succeq 0), \quad n \rightarrow \infty.$$

Observe also that

$$L_1 \leq \mathbf{1}(\rho \geq -M') \text{ for some } M' \geq 0.$$

To see this in more detail, choose $M' \geq 0$ such that $\min_{1 \leq j \leq d} a_0^{(j)} \geq -M'$ (the superscript (j) denotes ‘ j th component’ of a given vector). Fix ρ and θ such that $L_1 = 1$. Then for all j with $\theta^{(j)} > 0$,

$$\rho \geq \rho\theta^{(j)} = \rho\theta^{(j)} - a(R_{k,n})^{-1} R_{k,n} (S(\theta)^{(j)} - \theta^{(j)}) \geq a_0^{(j)} \geq -M'.$$

Note that $\theta \in H$ guarantees that at least one component in θ must be positive.

In what follows, we prove the assertion when $M' = 0$. The proof for a general M' is notationally more complicated, but essentially the same.

Before moving to L_4 , note the following useful expansion, which will be applied repeatedly in what follows: For each $i = 1, \dots, d$,

$$(6.10) \quad \left\| (R_{k,n} + a(R_{k,n})\rho)\theta + r_n y_i \right\| = R_{k,n} + a(R_{k,n}) \left(\rho + \frac{\langle \theta, y_i \rangle + \gamma_n(\rho, \theta, y_i)}{a(R_{k,n})/r_n} \right),$$

so that $\gamma_n(\rho, \theta, y_i) \rightarrow 0$ uniformly in $\rho \geq 0$, $\theta \in S^{d-1}$, and $\|y_i\| \leq M$ (M is determined in (2.7)).

Turning now to L_4 , we shall rewrite the expression within the indicator as follows:

$$(6.11) \quad \rho\theta + \frac{r_n}{a(R_{k,n})} \left(y_i + \frac{\alpha_n}{\beta_n} \right),$$

where

$$\alpha_n = (\langle \theta, y_i \rangle + \gamma_n(\rho, \theta, y_i))\theta + \frac{R_{k,n}}{r_n} \left(1 + \frac{a(R_{k,n})}{R_{k,n}} \rho \right) \theta - m \left(\frac{R_{k,n}}{r_n} \left(1 + \frac{a(R_{k,n})}{R_{k,n}} \rho \right) \theta + y_i \right)$$

with

$$m(x) = (|x^{(1)}|, \dots, |x^{(d)}|), \quad x = (x^{(1)}, \dots, x^{(d)}) \in \mathbb{R}^d,$$

and

$$\beta_n = 1 + \frac{a(R_{k,n})}{R_{k,n}} \left(\rho + \frac{\langle \theta, y_i \rangle + \gamma_n(\rho, \theta, y_i)}{a(R_{k,n})/r_n} \right).$$

As seen above, $L_1 \rightarrow 1$ ($\rho\theta \in I_0$, $\theta \succeq 0$) as $n \rightarrow \infty$, so it is enough to discuss the convergence of (6.11) for every $\rho \geq 0$, $\theta \succ 0$, and $\|y_i\| \leq M$. Then, for large enough n ,

$$\frac{R_{k,n}}{r_n} \left(1 + \frac{a(R_{k,n})}{R_{k,n}} \rho \right) \theta + y_i \succ 0.$$

Thus, we have that $\alpha_n \rightarrow \langle \theta, y_i \rangle \theta - y_i$ and $\beta_n \rightarrow 1$ as $n \rightarrow \infty$. Now we have

$$\rho\theta + \frac{r_n}{a(R_{k,n})} \left(y_i + \frac{\alpha_n}{\beta_n} \right) \rightarrow (\rho + c^{-1} \langle \theta, y_i \rangle) \theta$$

and in conclusion, for every $\theta \succ 0$,

$$L_4 \rightarrow \prod_{i=1}^{k-1} \mathbf{1} \left((\rho + c^{-1} \langle \theta, y_i \rangle) \theta \in I_i \right).$$

Regarding L_2 , it is clear that for every $\rho \geq 0$, $L_2 \rightarrow 1$ as $n \rightarrow \infty$ and it is also easy to check that $L_2 \leq 2(\rho \vee 1)^{d-1}$.

As for L_3 , we write

$$L_3 = L(R_{k,n})^{-1} L(R_{k,n} + a(R_{k,n})\rho) \exp \left\{ -\psi(R_{k,n} + a(R_{k,n})\rho) + \psi(R_{k,n}) \right\}.$$

An elementary calculation (e.g. p142 in [14]) shows that

$$(6.12) \quad \frac{a(R_{k,n})}{a(R_{k,n} + a(R_{k,n})v)} \rightarrow 1$$

uniformly on bounded v -sets. Namely $1/a$ is flat for a . Therefore, for every $\rho \geq 0$,

$$\exp \left\{ -\psi(R_{k,n} + a(R_{k,n})\rho) + \psi(R_{k,n}) \right\} \rightarrow e^{-\rho}, \quad n \rightarrow \infty.$$

Since L is flat for a , it follows that $L_3 \rightarrow e^{-\rho}$ as $n \rightarrow \infty$ for every $\rho \geq 0$. For the upper bound of L_3 on $\{\rho \geq 0\}$, we apply Lemma 6.4. Choosing $\epsilon \in (0, (d + \gamma k)^{-1})$ and recalling that ψ is non-decreasing,

$$\begin{aligned} & \exp\left\{-\psi(R_{k,n} + a(R_{k,n})\rho) + \psi(R_{k,n})\right\} \mathbf{1}(\rho \geq 0) \\ &= \sum_{m=0}^{\infty} \mathbf{1}(q_m(n) \leq \rho < q_{m+1}(n)) \exp\left\{-\psi(R_{k,n} + a(R_{k,n})\rho) + \psi(R_{k,n})\right\} \\ &\leq \sum_{m=0}^{\infty} \mathbf{1}(0 \leq \rho \leq \epsilon^{-1}e^{(m+1)\epsilon}) e^{-m} \end{aligned}$$

for all $n \geq N_\epsilon$.

On the other hand, using the bound in (4.3), on $\{\rho \geq 0\}$, we have, for sufficiently large n ,

$$L(R_{k,n})^{-1}L(R_{k,n} + a(R_{k,n})\rho) \leq C \left(1 + \frac{a(R_{k,n})}{R_{k,n}}\rho\right)^\gamma \leq 2C(\rho \vee 1)^\gamma.$$

Multiplying these bounds together, we have

$$L_3 \mathbf{1}(\rho \geq 0) \leq 2C(\rho \vee 1)^\gamma \sum_{m=0}^{\infty} \mathbf{1}(0 \leq \rho \leq \epsilon^{-1}e^{(m+1)\epsilon}) e^{-m}.$$

Next, we turn to L_5 . First, denote

$$(6.13) \quad \xi_n(\rho, \theta, y) = \frac{\langle \theta, y_i \rangle + \gamma_n(\rho, \theta, y)}{a(R_{k,n})/r_n}.$$

Since $c = \lim_{n \rightarrow \infty} a(R_{k,n})/r_n$ is strictly positive,

$$(6.14) \quad A = \sup_{\substack{n \geq 1, \rho \geq 0, \\ \theta \in S^{d-1}, \|y\| \leq M}} |\xi_n(\rho, \theta, y)| < \infty.$$

Using the expansion (6.10), we can write

$$\begin{aligned} L_5 &= \prod_{i=1}^{k-1} L(R_{k,n})^{-1} L\left(R_{k,n} + a(R_{k,n})(\rho + \xi_n(\rho, \theta, y_i))\right) \\ &\quad \times \exp\left\{-\int_0^{\rho + \xi_n(\rho, \theta, y_i)} \frac{a(R_{k,n})}{a(R_{k,n} + a(R_{k,n})r)} dr\right\}. \end{aligned}$$

Due to the uniform convergence (6.12) and (6.14), for every $\rho \geq 0$, $\theta \in S^{d-1}$, and $\|y_i\| \leq M$,

$$\int_0^{\rho + \xi_n(\rho, \theta, y_i)} \frac{a(R_{k,n})}{a(R_{k,n} + a(R_{k,n})r)} dr \rightarrow \rho + c^{-1}\langle \theta, y_i \rangle, \quad n \rightarrow \infty$$

and

$$L(R_{k,n})^{-1} L\left(R_{k,n} + a(R_{k,n})(\rho + \xi_n(\rho, \theta, y_i))\right) \rightarrow 1, \quad n \rightarrow \infty.$$

We thus conclude that

$$L_5 \rightarrow \exp\left\{-(k-1)\rho - c^{-1} \sum_{i=1}^{k-1} \langle \theta, y_i \rangle\right\}$$

for every $\rho \geq 0$, $\theta \in S^{d-1}$, and $\|y_i\| \leq M$, $i = 1, \dots, k-1$.

To provide an appropriate upper bound for L_5 on $\{\rho \geq 0\}$, note that, for large enough n ,

$$\begin{aligned} & \prod_{i=1}^{k-1} \exp\left\{-\int_0^{\rho + \xi_n(\rho, \theta, y_i)} \frac{a(R_{k,n})}{a(R_{k,n} + a(R_{k,n})r)} dr\right\} \mathbf{1}(\rho \geq 0) \\ & \leq \exp\left\{\sum_{i=1}^{k-1} \int_{-A}^0 \frac{a(R_{k,n})}{a(R_{k,n} + a(R_{k,n})r)} dr \mathbf{1}(-A \leq \rho + \xi_n(\rho, \theta, y_i) \leq 0)\right. \\ & \quad \left.- \sum_{i=1}^{k-1} \int_0^{\rho + \xi_n(\rho, \theta, y_i)} \frac{a(R_{k,n})}{a(R_{k,n} + a(R_{k,n})r)} dr \mathbf{1}(\rho + \xi_n(\rho, \theta, y_i) > 0)\right\} \\ & \leq e^{2A(k-1)}. \end{aligned}$$

It follows from (4.2) and (4.3) that there exists $C_1 \geq 1$ such that, on $\{\rho \geq 0\}$,

$$\begin{aligned} & L(R_{k,n})^{-1} L\left(R_{k,n} + a(R_{k,n})(\rho + \xi_n(\rho, \theta, y_i))\right) \\ & = L(R_{k,n})^{-1} L\left(R_{k,n} + a(R_{k,n})(\rho + \xi_n(\rho, \theta, y_i))\right) \mathbf{1}(\rho + \xi_n(\rho, \theta, y_i) \geq -A) \\ & \leq 2 + L(R_{k,n})^{-1} L\left(R_{k,n} + a(R_{k,n})(\rho + \xi_n(\rho, \theta, y_i))\right) \mathbf{1}(\rho + \xi_n(\rho, \theta, y_i) > 0) \\ & \leq 2 + C \left(1 + \frac{a(R_{k,n})}{R_{k,n}}(\rho + \xi_n(\rho, \theta, y_i))\right)^\gamma \\ & \leq 2 + 2C \left(1 \vee (\rho + \xi_n(\rho, \theta, y_i))\right)^\gamma \\ & \leq C_1^{(k-1)^{-1}} (\rho \vee 1)^\gamma \end{aligned}$$

for sufficiently large n . This in turn implies that

$$\prod_{i=1}^{k-1} L(R_{k,n})^{-1} L\left(R_{k,n} + a(R_{k,n})(\rho + \xi_n(\rho, \theta, y_i))\right) \leq C_1 (\rho \vee 1)^{\gamma(k-1)}$$

on $\{\rho \geq 0\}$, and further,

$$L_5 \leq C_1 e^{2A(k-1)} (\rho \vee 1)^{\gamma(k-1)}$$

holds on $\{\rho \geq 0\}$.

Finally, we turn to L_6 .

$$\begin{aligned} -\log L_6 &= np\left((R_{k,n} + a(R_{k,n})\rho)\theta, (R_{k,n} + a(R_{k,n})\rho)\theta + r_n \mathbf{y}; r_n\right) \\ &= nr_n^d f(R_{k,n} e_1) \int_{B(0;2) \cup \bigcup_{i=1}^{k-1} B(y_i;2)} f(R_{k,n} e_1)^{-1} \\ &\quad \times f\left(\left(R_{k,n} + a(R_{k,n})(\rho + \xi_n(\rho, \theta, z))\right)e_1\right) dz. \end{aligned}$$

As argued in the derivation of the bound for L_5 , the supremum of integrand over n can be bounded by a constant multiple of $(\rho \vee 1)^\gamma$. On the other hand, (4.5) guarantees $nr_n^d f(R_{k,n} e_1) \rightarrow 0$ as $n \rightarrow \infty$ and hence, $L_6 \rightarrow 1$ as $n \rightarrow \infty$.

From the argument thus far, it follows that for every $\rho \geq 0$, $\theta \in S^{d-1}$, and $\|y_i\| \leq M$, $i = 1, \dots, d$,

$$\begin{aligned} \prod_{i=1}^6 L_i &\rightarrow e^{-k\rho - c^{-1} \sum_{i=1}^{k-1} \langle \theta, y_i \rangle} \\ &\quad \times \mathbf{1}(\rho\theta \in I_0, \theta \succeq 0, (\rho + c^{-1} \langle \theta, y_i \rangle)\theta \in I_i, i = 1, \dots, k-1). \end{aligned}$$

To finish the argument, it remains to check the L^1 -integrability on $\{\rho \geq 0\}$ of the upper bound for $\prod_{i=1}^6 L_i$. As we have seen so far,

$$\begin{aligned} &\prod_{i=1}^6 L_i \mathbf{1}(\rho \geq 0) \\ &\leq 4CC_1 e^{2A(k-1)} (\rho \vee 1)^{d-1+\gamma k} \sum_{m=0}^{\infty} \mathbf{1}(0 \leq \rho \leq \epsilon^{-1} e^{(m+1)\epsilon}) e^{-m} \end{aligned}$$

for sufficiently large n . Indeed,

$$\int_0^\infty (\rho \vee 1)^{d-1+\gamma k} \sum_{m=0}^{\infty} \mathbf{1}(0 \leq \rho \leq \epsilon^{-1} e^{(m+1)\epsilon}) e^{-m} d\rho$$

$$\leq \frac{e^{(d+\gamma k)\epsilon}}{\epsilon^{d+\gamma k}} \sum_{m=0}^{\infty} e^{-[1-(d+\gamma k)\epsilon]m}$$

so that the right-hand side is finite because we took $0 < \epsilon < (d + \gamma k)^{-1}$. Applying the dominated convergence theorem as well as (4.5), it turns out that $J_k \rightarrow \nu_k(K)$, $n \rightarrow \infty$ as required.

Part 3: Next, we shall prove that (2.18) is satisfied. For $l = 1, \dots, k-1$, and any compact set $K \subset E_{2k-l} = ((-\infty, \infty]^d)^{2k-l}$, there exists $B \geq 0$ such that

$$K \subset \{(x_1, \dots, x_{2k-l}) \in (\mathbb{R}^d)^{2k-l} : x_i \succeq -B\mathbf{1}, i = 1, \dots, 2k-l\},$$

where $\mathbf{1}$ is a d -dimensional vector with all entries 1. Then, the probability in (2.18) can be bounded by

$$\begin{aligned} & n^{2k-l} \mathbb{P}\{h_n(\mathcal{X}_k) = 1, h_n(X_1, \dots, X_l, X_{k+1}, \dots, X_{2k-l}) = 1, \mathcal{X}_{2k-l}^{(n)} \succeq -B\mathbf{1}\} \\ &= n^{2k-l} \int_{(\mathbb{R}^d)^{2k-l}} h_n(x_1, \dots, x_k) h_n(x_1, \dots, x_l, x_{k+1}, \dots, x_{2k-l}) \\ &\quad \times \mathbf{1}\left(x_i - R_{k,n}S(x_i) \succeq -a(R_{k,n})B\mathbf{1}, i = 1, \dots, 2k-l, x_1/\|x_1\| \in H\right) \\ &\quad \times f(x_1) \dots f(x_{2k-l}) dx + o(1), \quad n \rightarrow \infty. \end{aligned}$$

The equality above follows from the fact that $X_1/\|X_1\| \in H^c$ and $X_1 - R_{k,n}S(X_1) \geq -a(R_{k,n})B\mathbf{1}$ do not occur simultaneously.

By precisely the same change of variables and polar coordinate transform as in the proof of (2.19), the leading term of the last line above equals

$$\begin{aligned} & n^{2k-l} r_n^{d(2k-l-1)} a(R_{k,n}) R_{k,n}^{d-1} f(R_{k,n}e_1)^{2k-l} \\ & \times \int_{(\mathbb{R}^d)^{2k-l-1}} \int_{S^{d-1}} \int_0^\infty \mathbf{1}\left(\rho\theta - \frac{R_{k,n}}{a(R_{k,n})}(S(\theta) - \theta) \succeq -B\mathbf{1}, \theta \in H\right) \\ & \times \left(1 + \frac{a(R_{k,n})}{R_{k,n}}\rho\right)^{d-1} f(R_{k,n}e_1)^{-1} f\left((R_{k,n} + a(R_{k,n})\rho)e_1\right) \\ & \times \prod_{i=1}^{2k-l-1} \mathbf{1}\left(\rho\theta + \frac{r_n}{a(R_{k,n})}y_i \right. \\ & \quad \left. - \frac{R_{k,n}}{a(R_{k,n})}\left[S\left((R_{k,n} + a(R_{k,n})\rho)\theta + r_n y_i\right) - \theta\right] \succeq -B\mathbf{1}\right) \\ & \times f(R_{k,n}e_1)^{-1} f\left(\|(R_{k,n} + a(R_{k,n})\rho)\theta + r_n y_i\|e_1\right) \\ & \times h(0, y_1, \dots, y_{k-1}) h(0, y_1, \dots, y_{l-1}, y_k, \dots, y_{2k-l-1}) d\rho J(\theta) d\theta dy. \end{aligned}$$

The asymptotic order of the above expression is

$$\mathcal{O}\left(n^{2k-l} r_n^{d(2k-l-1)} a(R_{k,n}) R_{k,n}^{d-1} f(R_{k,n} e_1)^{2k-l}\right),$$

which vanishes as $n \rightarrow \infty$ for every $l = 1, \dots, k-1$, and so the proof of (i) is complete.

Proof of statement (ii)

We need only show that, as $n \rightarrow \infty$,

$$N_n^{(k)}(f) = \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} h_n(\mathcal{X}_{\mathbf{i}}) f(\mathcal{X}_{\mathbf{i}}^{(n)}, \mathbf{i}/|\mathcal{P}_n|) \xrightarrow{p} 0$$

for every continuous non-negative function $f : E_k \times L_k \rightarrow \mathbb{R}_+$ with compact support. Note that the support of f is contained in

$$\{(x_1, \dots, x_k) \in (\mathbb{R}^d)^k : x_i \succeq -B_1 \mathbf{1}, i = 1, \dots, k\} \times L_k$$

for some $B_1 \geq 0$. Therefore,

$$N_n^{(k)}(f) \leq \|f\|_{\infty} \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} \mathbf{1}(h_n(\mathcal{X}_{\mathbf{i}}) = 1, \mathcal{X}_{\mathbf{i}}^{(n)} \succeq -B_1 \mathbf{1}).$$

Observe that $X_{i_j} - R_{k,n} S(X_{i_j}) \succeq -a(R_{k,n}) B_1 \mathbf{1}$ implies

$$\|X_{i_j}\| - R_{k,n} \geq -a(R_{k,n}) B_2$$

for some $B_2 \geq B_1$. Hence,

$$\begin{aligned} N_n^{(k)}(f) &\leq \|f\|_{\infty} \sum_{\mathbf{i} \in \mathcal{I}_{|\mathcal{P}_n|, k}} \mathbf{1}(h_n(\mathcal{X}_{\mathbf{i}}) = 1, \\ &\quad \|X_{i_j}\| - R_{k,n} \geq -a(R_{k,n}) B_2, j = 1, \dots, k). \end{aligned}$$

In view of Lemma 6.1 in the Appendix, what now needs to be verified is that

$$n^k \mathbb{P}\{h_n(\mathcal{X}_k) = 1, \|X_i\| - R_n \geq -a(R_{k,n}) B_2, i = 1, \dots, k\} \rightarrow 0.$$

Once again, applying the same kind of change of variables and polar coordinate transform, together with (6.10),

$$\begin{aligned} &n^k \mathbb{P}\{h_n(\mathcal{X}_k) = 1, \|X_i\| - R_n \geq -a(R_{k,n}) B_2, i = 1, \dots, k\} \\ &= n^k r_n^{d(k-1)} a(R_{k,n}) R_{k,n}^{d-1} f(R_{k,n} e_1)^k \int_{(\mathbb{R}^d)^{k-1}} \int_{S^{d-1}} \int_{\rho \geq -B_2} \left(1 + \frac{a(R_{k,n})}{R_{k,n}} \rho\right)^{d-1} \end{aligned}$$

$$\begin{aligned} & \times f(R_{k,n}e_1)^{-1} f\left((R_{k,n} + a(R_{k,n})\rho)e_1\right) \prod_{i=1}^{k-1} \mathbf{1}(\rho + \xi_n(\rho, \theta, y_i) \geq -B_2) \\ & \times f(R_{k,n}e_1)^{-1} f\left((R_{k,n} + a(R_{k,n})(\rho + \xi_n(\rho, \theta, y_i)))e_1\right) h(0, \mathbf{y}) d\rho J(\theta) d\theta d\mathbf{y}, \end{aligned}$$

where the definition of $\xi_n(\rho, \theta, y_i)$ is given by (6.13).

As argued before,

$$\left(1 + \frac{a(R_{k,n})}{R_{k,n}}\rho\right)^{d-1} \leq 2(\rho \vee 1)^{d-1}$$

and, on $\{\rho \geq -B_2\}$,

$$L(R_{k,n})^{-1} L(R_{k,n} + a(R_{k,n})\rho) \leq 2C(\rho \vee 1)^\gamma.$$

Furthermore, since a is eventually non-increasing,

$$\exp\left\{-\psi(R_{k,n} + a(R_{k,n})\rho) + \psi(R_{k,n})\right\} \leq e^{-\rho}.$$

As argued before, it follows from (4.2) and (4.3) that there exists $C_2 > 0$ such that on $\{\rho \geq -B_2, \rho + \xi_n(\rho, \theta, y_i) \geq -B_2\}$,

$$\prod_{i=1}^{k-1} L(R_{k,n})^{-1} L(R_{k,n} + a(R_{k,n})(\rho + \xi_n(\rho, \theta, y_i))) \leq C_2(\rho \vee 1)^{\gamma(k-1)}.$$

Since a is eventually non-increasing,

$$\begin{aligned} & \prod_{i=1}^{k-1} \exp\left\{-\psi(R_{k,n} + a(R_{k,n})(\rho + \xi_n(\rho, \theta, y_i))) + \psi(R_{k,n})\right\} \\ & \leq \prod_{i=1}^{k-1} \exp\left\{-(\rho + \xi_n(\rho, \theta, y_i))\right\}. \end{aligned}$$

Now, we have

$$\begin{aligned} & n^k \mathbb{P}\{h_n(\mathcal{X}_k) = 1, \|X_i\| - R_n \geq -a(R_{k,n})B_2, i = 1, \dots, k\} \\ & \leq 4CC_2 \int_{(\mathbb{R}^d)^{k-1}} \int_{S^{d-1}} \int_{\rho \geq -B_2} (\rho \vee 1)^{d-1+\gamma k} e^{-\rho} \prod_{i=1}^{k-1} \exp\left\{-(\rho + \xi_n(\rho, \theta, y_i))\right\} \\ & \quad \times \mathbf{1}(\rho + \xi_n(\rho, \theta, y_i) \geq -B_2) h(0, \mathbf{y}) d\rho J(\theta) d\theta d\mathbf{y}. \end{aligned}$$

If we can show that

$$(6.15) \quad \exp\left\{-\left(\rho + \xi_n(\rho, \theta, y_i)\right)\right\} \mathbf{1}(\rho + \xi_n(\rho, \theta, y_i) \geq -B_2) \rightarrow 0, \quad n \rightarrow \infty$$

for every $\rho \geq -B_2$, $\theta \in S^{d-1}$, and $\|y_i\| \leq M$, $i = 1, \dots, d$, then the dominated convergence theorem finishes the proof. First, in the case of $\langle \theta, y_i \rangle < 0$,

$$\rho + \xi_n(\rho, \theta, y_i) \rightarrow -\infty, \quad n \rightarrow \infty$$

and hence, as $n \rightarrow \infty$,

$$\begin{aligned} & \exp\left\{-\left(\rho + \xi_n(\rho, \theta, y_i)\right)\right\} \mathbf{1}(\rho + \xi_n(\rho, \theta, y_i) \geq -B_2) \\ & \leq e^{B_2} \mathbf{1}(\rho + \xi_n(\rho, \theta, y_i) \geq -B_2) \rightarrow 0. \end{aligned}$$

Second, if $\langle \theta, y_i \rangle > 0$, then $\exp\left\{-\left(\rho + \xi_n(\rho, \theta, y_i)\right)\right\} \rightarrow 0$. So in either case, (6.15) is established. $\square$

Acknowledgement. The authors are grateful to two referees and an associate editor, all of whose comments led to a substantial improvement in the presentation of the paper.
